CHEMICAL & METALLURGICAL ENGINEERING

A Weekly Technical Newspaper

Including the Incorporation of Electrochemical and Metallurgical Industry and Iron and Steel Magazine

McGraw-Hill Company, Inc., New York City

Volume XXVI

January 1 to June 30, 1922

436851
3.7.45

GENERAL ALPHABETICAL INDEX

PAGES

Jan. 4 ..... to 45
Jan. 11 ..... 97 to 00
Jan. 18 ..... 145 to 3

A

Abrasives, Removing iron and tit[illegible] from (P.) ..... [illegible]
Absorption:
——Of gasoline from natural gas 798
——Of NH_3 in H_2SO_4 (B. P.) ..... [illegible]
Acetic Acid for munitions, French [illegible] ment may co-operate in deve[illegible] 735 896
Acetaldehyde, Alcohol from (P.) ..... [illegible]
Acetylene, Chlorinating (B. P.) ..... [illegible] 808
Accidents involving ammonium [illegible] 799
Munroe ..... [illegible] 991
"Achema" in Hamburg in Jun[illegible] ate. 537
ACID:
——Acetic, Distillation of (N[illegible] 616
——Corrosion in heat exchan[illegible] fining. Matthews and [illegible] 729
——Corrosion losses of metals [illegible] land 1120
——Hydrocyanic, Replacement [illegible] fumigation. Espenhahn 1166
——Mucic, Commercial prepa[illegible] CN in
——Nitric. See Nitric. 939
——Must lower freight on [illegible] of 1118
——Plant operation, Grap[illegible] Rupard 709
——Plants, Losses in. W[illegible] ord of.
——Production of princi[illegible] 365
——Proof masonry. Gilch[illegible] 974
——Resistant brick usec[illegible] istics.. 329
Larison ..... [illegible] 1162
——Still, Plate efficienc[illegible] naconda.
——Sulphuric. See Sul[illegible] 836
——Symposium planned [illegible] 730
ing of Americ[illegible]
Chemical Enginee[illegible] ner meet-
——Symposium, Progra[illegible] itute of
Action of Senate Financ[illegible] 471
tending embargo[illegible] 850
features ..... [illegible] tee in ex-
Activators for preparin[illegible] couraging water pastes [illegible] 707
Admiralty brass, casti[illegible] gents from Cammen ..... [illegible] 944
Advertisers will discu[illegible] ser tubing.
Advertising chemica[illegible] 356
worth ..... [illegible] ting 1089
Africa:
——New steel deve[illegible] 920
——Steel industry i[illegible]
Agricultural: [illegible] roposed ... 904
——And fertilizer [illegible] 1030
ing views o[illegible]
——Prices, Collap[illegible] record oppos-
Air: [illegible] shoals. 278
——Reduction Co[illegible] 137
—— Annual re[illegible]
—— Shows inc[illegible]
ter 19[illegible] 475
——Uses of in [illegible] ing first quar-
——Lift:
—— Bihn-Jon[illegible] facture. Stone.. 607
ment, [illegible]
[illegible] huric acid. Com- 534

AIR LIFT—*Continued:*
—— Supplies cold water for tire manufacture. Stone 606
Akron to entertain A.C.S. sections.... 712
Alby Carbide Co. goes into liquidation.... 487

ALCOHOL:
——Calculations of rectifying column size (N.) 729
——Committee of A.C.S. 196
——Exposibility limits of air mixtures. Dodge 416
——From aldehydes (B. P.) 991
——From acetaldehyde (P.)..... 799
——From Western larch (N.) 738
——Industry, Trade association of formed in Italy 1061
——Mixture for motor fuel 1118
——Regulations. Distributing agencies violated in Fleischmann case 520
——Regulations on sale of 306
——To assist legitimate users of. Tunison 196
——Unique industry (N.) 518
——U. S. Industrial reports deficit..... 810

ALIEN:
——Employees banned by leather company 182
——Property:
—— Custodian activities, King would investigate 853
—— Custodian reports activities 807
—— Custodian would welcome investigation 1139
—— Report called for by Senate..... 184

ALKALI:
——Company reduces wages..... 521
——Cyanides from HCN (B. P.)..... 897
——Manufacturers ask lower freight rates 328
——Silicates (B. P.)..... 944
Allied Chemical and Dye Corp. annual report 810
Allotropic sulphur 55

ALLOYS:
——Aluminum:
—— And silicon. Jeffries..... 750
—— Heat-treatment of (P.) 370
—— High strength 689
—— Request foundry sand data on.... 1139
——And metals low in carbon (B. P.)... 944
——"A," properties of 691
——Course in at Wisconsin 807
——For handling molten glass (B. P.)... 800
——Grain growth in. Jeffries and Archer. 410
——Iron: carbon, Brinell hardness of 562
——Light, Elektron (S.) 798
——Melting furnaces for 1110
——Non-ferrous, Recent work on (N.).. 983
——Report, 11th of I.M.E..... 689
——Technical control in the foundry (N.) 1109
——Titanium (S.) 324
——White (S.) 1182
——Y (Al-Cu-Ni-Mg) 785
Alkaloids, Hydrogenation of (S.)..... 370
Allied Chemical & Dye Corporation report. 475
Allotropy of iron. Alexander..... 201
Alphanaphthalene for flotation. Ralston and Wichmann 501
Alum, Residual, in filtered water. Buswell and Edwards 826
Alumina:
——Coagulation process, water filtration. Buswell and Edwards 826
——Extraction from Cuban iron ores. Hayward 261
——Hydrates of (N.) 489
——Process (P.)..... 1183
Aluminous abrasives (P.) 798

ALUMINUM:
——Alloys:
—— Contraction of (N.) 983
—— For use at high temperatures 689
—— Foundry sand data wanted 1139
—— Heat-treatment of (P.) 370
—— Melting furnaces for 1110
—— Treatment of (B. P.) 85
—— Y alloy 785
——Bronze, Heat-treatment of. Comment. Comstock. Also Woyski 388
—— Reply. Blue 389
——As carrier for catalyst (B. P.)..... 226

ALUMINUM—*Continued:*
——Brittleness developed in, by stress and corrosion. Rawdon, Krynitsky, Berliner 154
——Chloride:
—— Anhydrous, from carbide (P.) ... 608
—— From bauxite by treatment with S and Cl_2 (P.)..... 563
——Company sues on Nitro sale..... 1045
——Compounds in coal tar. Morgan and Soule 978
——Compressed, Recrystallization diagram for. Holz 580
——Consumption of electrodes in manufacture of. Yardley 322
——Corrosion of purc. Rawdon, Krynitsky and Berliner 154
——Deposits in Guianas. Wilson..... 746
——Industry of Switzerland..... 1033
——Production in 1921 1125
——Recrystallization of. Jeffries and Archer 405
——Salts (B. P.) 800
——Silicon alloys. Jeffries 751
——Single crystals of, Properties of (S.). 514
——Sulphate, Corrosive action on iron and steel. Strickland 1167
——Use as deoxidizer in steel making (P.) 563
——Welding, Flux for (B. P.)..... 225

AMERICAN CERAMIC SOCIETY:
——Program, St. Louis 133
——Annual meeting 488
——Election of officers 488
——Enamels division plans research on enameled cast iron 1140
——Moves headquarters 136
——Offers aid to glass research..... 279
——Plans summer trip to England and Europe 854

AMERICAN CHEMICAL SOCIETY:
——Birmingham meeting 724
—— Program 609
—— Council meeting 724
—— General meetings 725
——Chicago Section. See Chicago.
——Committee on society procedure appointed to improve organization.. 899
——Gas and fuel section new feature.... 1140
——Joint meeting of Middle Western sections:
—— Program announced 470
—— Report. Howe and Wendt..... 567
——Milwaukee section hears Wikoff on felt hats (N.)..... 902
——Petroleum research committee appointed 901
——Plans for Pittsburgh meeting..... 1224
——Plans trip as preliminary to convention 376
American chemists—a statistical study. Wendt 112
American Dyes Institute:
——Defended by Danner 519
American Dyes Institute. King questions motives of 467

AMERICAN ELECTROCHEMICAL SOCIETY:
——Announces spring meeting plans.... 421
——Baltimore meeting announced 711
——Baltimore meeting 820, 873
——Election of officers 1922-1923..... 879
——Electrodeposition division 880
——Officers appointed. Symposiums planned for spring meeting 1140
——Subjects of future meetings 879
Ambitious program of activities outlined for Institute of American Meat Packers 1091
American Engineering Council:
——Holds first annual meeting 134
——Statistics on unemployment 474
American Engineering Standards Committee:
——Co-operates with Hoover 1139
——Wants analytical information 853
American Fertilizer Association plan meeting 807

AMERICAN FOUNDRYMEN'S ASSOCIATION:
——Changes convention plans 228
——Molding sand research 662
——Plans work on molding sand 133

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis;
(N.)—Papers read at society meetings but not printed in full.

INDEX

AM. FOUNDRYMEN'S ASSN.—*Continued:*
——Rochester meeting:
—— Program 900
—— Report of 1107

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS:
——Conference on chemical engineering education:
—— Plans 854
—— Meeting 994
——Niagara Falls meeting:
—— Plans 471
—— Program 850
—— Final program 1080
——Report on atmospheric pollution. Withrow 975

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS:
——Co-operates with government in survey of municipal resources 806

AMERICAN INSTITUTE OF METALS:
—— Program for Feb., 1922 86
—— Meeting, Feb., 1922 391
—— Rochester program 805
—— Rochester meeting 1107
——New York (125th) meeting:
—— Program 229
—— Report 391
——Work on non-ferrous alloys (N.) 983

AMERICAN IRON AND STEEL INSTITUTE:
——General meeting, New York 1014
American Leather Chemists' Society:
——Program announced for Canadian meeting 1092
——To hold summer meeting in Canada .. 854
American Linseed Co. shows deficit 618
American Metal Co. report 1192
American Oil Chemists' Society:
——Meeting postponed 902
——Report of meeting 1186

AMERICAN PETROLEUM INSTITUTE:
——Estimated production 954
——Statistics on production 1921 282
——Scale for reporting gravity of liquid petroleum products 1120
American potash in 1921 282
American Smelting & Refining shows smaller income 762

AMERICAN SOCIETY OF MECHANICAL ENGINEERS:
——Atlanta program 806
——Chicago section told of insulation research 614
——Meeting to be followed by exposition. 760
——Will discuss power test codes 854

AMERICAN SOCIETY FOR STEEL TREATING:
——Changes meeting plans 279
——New England and Seaboard chapters, New York 377
——Organizes metallurgy course 279
——Pittsburgh meeting program 805
——Regional meeting in Pittsburgh 1062
——Sectional meeting, New York 437
——Washington chapter, comparison of crucible steels (N.) 229
——Washington chapter, metal failures (N.) 853

AMERICAN SOCIETY FOR TESTING MATERIALS:
——Announces program for Atlantic City meeting 902
——Howe's service as president of 1017
——Methods of analysis information desired 853
——Report on investigation of P and S in steel. Thum 1019
American valuation, believed impractical .. 851
American valuation, Finance Committee favors 277
American Welding Society issues first "Proceedings" 328
Amidophenol, Electrolytic preparation of (N.) 877

AMMONIA:
——Absorption at Oppau and Sheffield. Tour. IV 413
——And coal-tar products from steel works. Clark 8
——Claude process for (N.) 59
——Cracker for moderate scale testing of catalysts. Tour 589
——Cracker. Larson, Newton and Hawkins 494
——Effect of on deposition of iron. McMahon 641
——Oxidation, absorption of HNO_3 (B. P.) 705
——Oxidation of (S.) 704
——Oxidation. Some economic aspects of. Taylor 1217
——Purification of. Symmes 1070
——Recovery from shale-oil distillation. Jones 551
——Works liquors. Removal of phenols from. (B. P.) 992

AMMONIA, SYNTHETIC:
——Catalyst bomb (B. P.) 1183
——Contributions to study of. Fixed Nitrogen Research Laboratory 493, 555, 588, 647, 683
——Converters at Oppau. Tour IV 411
——Cost of at Oppau. Tour 463
——Effect of various operating factors on conversion. Larson and Tour 649
——In Germany 212
——Muscle Shoals. Weeks analyzes Ford offer 272
——New German plant 709
——Nomenclature. Larson and T
——Plant explosion ..... F
——Plants, German and Ame
Tour ..... F

——Problem from various viewpoi
Tour G1
——Purification of N: H mixture f
Haber process. Tour .....
——Tour addresses Affiliated Technical Societies of Detroit on .....

AMMONIUM NITRATE:
——As a fertilizer. Tolman .....
——Explosibility of. Munroe .....
——Explosibility of synthetic, subject of study .....
——As absorbent medium in ammonia refrigeration. (S.) .....
——Manufacture of. Symmes .....
——Off free list .....
——Recent tests of. Munroe .....
——Thermal decomposition of. Munroe.

AMMONIUM SULPHATE:
——From Muscle Shoals, views of fertilizer interests 27
——Neutralization. (B. P.) 89
——Proposed manufacture at Muscle Shoals. Tolman 465
——Removing cyanogen from Gas. (B. P.) 226
——Saturator for. (B. P.) 1043
——Surplus of pointed out by fertilizer interests 423
——Surplus only temporary, says Whitney 423
Analysis of sublimed white lead graphically. Paxton 989
Analysis, Cost of in state laboratory 521
Analytical control of ammonia sythesis. Larson and Brooks 560
Anderson, Sydney, on basic difficulties undermining business 953
Anhydrous aluminum chloride. (P.) 608
Annual:
——Conference on weights and measures, program 949
——Reports and dividend announcements 475
——Reports and financial statements 378
Anthracene:
——Cancer from handling 497
——Production 114
——Refining. (B. P.) 801
Antimony:
——Effect of, on electrolytic refining of zinc. Scholl 596
——Field to be location of paint plant ... 1141
——Production of Latin America,, Wilson 746
Anthraquinone. Hydroxyquinones from. (B. P.) 944
Anthraquinone, Purification of. (B. P.) .. 896
Apparatus for superphosphate manufacture. (P.) 563
Appleby bill, water pollution 376, 613
Appleby bill, Discussion 568
Appleby resolution passes House 1141
Application of electrical precipitation to the wood-distillation process. Hawley and Pier 1031
Application of Muscle Shoals power to chemical process denounced 470
April wholesale prices 1002
April's progress toward better business .. 856
Arc-process nitrate plants may be established by Norwegian Government .. 613
Argall, Philip. Comment. Palmer 677
Armco iron, grain growth of. Jeffries and Archer 404
Armour Leather Co., annual report 379
Arms conference and chemical warfare. McBride 351
Army engineers urge hydro-electric development of Tennessee River 1046
Arsenic:
——Effect of, on electrolytic refining of zinc. Scholl 595
——Long tariff debate on 951
——Manufacture. Ambruster 1155
——Production of Mexico. Wilson 749
——Situation, and arsenic for boll weevil. Ambruster 1155
——Uses of. Ambruster 1156
Arsenic Compounds, Organic:
——Tanning with. (B. P.) 705
Asbestos insulating material, Manufacture of. (B. P.) 325
Ash:
——Fusibility of 732
——Removal by froth flotation. Ralston and Yamada 1084

ASPHALT:
——Deposits of Latin America. Wilson .. 747
——Destructive distillation of. Botkin .. 447
——From shale-oil residues. Jones 553
——General Co. Shows Deficit 234
——Refation of shale oil residue to. Botkin 445
Associated Technical Societies of Detroit organized 184
Association of Chemical Equipment Manufacturers announces committee on exposition plans 1047
Association of Chemical Plant Equipment Manufacturers will organize 712
Aston, Work of on isotopes. Hendrick .. 587
Atlantic Refining Co., New financing 1192
Atlas Powder Co. annual report 475
Atmospheric nitrogen production in Germany 212
Atmospheric pollution. Limit on smelter stacks 519
Atmospheric pollution from sulphuric acid plant fumes. Withrow 972
——Comment. Correction 1106

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis;
(N.)—Papers read at society meetings but not printed in full.

...integration of Tungsten:
...ent. Goetschius .....
...Wendt 676
...sts joint meeting of Mid-West ... 772
...C.S. sections .....
...numbers and atomic weights.
...Hendrick 567
...and isotopes. Hendrick 585
...nite transformed to martensite. Bain 544

...TRALIA:
——Glass industry expanding 127
——To investigate paper pulp sources in ...ustrian chemical industries 884
...utomatic load regulator for motor-driven pulp grinders. Artz 918
Automatic temperature control. (N.) 363

B

Back ionization in electric precipitator. Anderson 852
Badische reports increased earnings 151
Bad paint and good medicine. Comment. Buchanan 1047
Bakelite:
——As insulation. (B. P.) 964
——Merger 226
——Patents established 1184
Baking industry, Application of chemistry to. (N.) 996
Baking powder. Meckstroth 566
Ball mill, classifies ground material. (B. P.) 224
Barium chloride in mfr. of H_2O_2. Doerner 705
...rium hydrate. (B. P.) 1111
...rytes, Use as filler 944
...skerville memorial planned 410
...TTERIES: 614
...—Standard sizes proposed 178
...—Tests for 179
...—SECONDARY:
Effect of impurities on. (N.) ... 875
Storage, Effect of impurities on. Gillette 981

BOOK REVIEWS—*Continued:*
——Findley and Wigginton. The Practical Chemistry of Coal and Its Products 801
——Gas Chemists' Handbook 993
——Gilbert and Pogue. America's Power Resources 992
——Grard. Aluminum and Its Alloys... 801
——Guillet. The Destruction of the French Metallurgical Plants by the Germans (Nos Usines Metallurgiques Devastees) 83
——Hackh. Chemical Reactions and Their Equations 371
——Hale. The Distribution of Gas.... 706
——Hall and Williams. The Chemical and Metallographic Examination of Iron, Steel and Brass..... 516
——Ibbotson. The Chemical Analysis of Steel-Works Materials 83
——Ketchum. Steel Mill Buildings.... 657
——Korzybski. The Manhood of Humanity, The Science and Art of Human Engineering 37
——Lowry and Downey. Study Questions in Organic Chemistry 945
——Meade. Modern Gasworks Practice.. 898
——Millard. Physical Chemistry for Colleges 993
——Mills. Materials of Construction, Their Manufacture and Properties. 897
——Murke. Condensed Description of the Manufacture of Beet Sugar..... 657
——Parr. Analysis of Fuel, Gas, Water and Lubricants 945
——Pogue. Economics of Petroleum.... 706
——Prout. A Life of George Westinghouse 371
——Robinson. The Elements of Fractional Distillation 898
——Scott. Journal of the Institute of Metals 657
——Tammann. Lehrbuch der Metallographie 1135
——Thorpe. A Dictionary of Applied Chemistry 1134
——Venable. Zirconium and Its Compounds 992
——Voisin. Precious Metals..... 801
——Watts. An Introduction to the Psychological Problems of Industry.. 84
Booth rotating electric furnace. (N.).... 822
Borates in 1921..... 1220

BORAX:
——And boric acid. (B. P.) 896
——Production of Latin America. Wilson 748
Borings, Cast iron, Melting. (N.)..... 822
Borneol, Preparation of. (B. P.)..... 991
Boron steel 169

BRASS:
——Alpha, grain growth of in solid state. Jeffries and Archer 403
——And white metal, Colloidal state in. Alexander 170
——Cartridge, Physical properties of. (N.) 1108
——Corrosion in. Comment. Cushman.. 773
——Corrosion, Results of committee, British Institute of Metals. Thum. 301
——Crystallization of. Jeffries and Archer 402
——Dip brazing with 80:20. Schaal.... 1121
——Effect of composition on corrosion. Comment. Davidson 773
——Engine. (N.) 1109
——Etching. Campbell 1164
——Foundry, Electric furnace in English. 744
——Melting furnace. (N.) 1110
——Hardness of. Jeffries and Archer... 405
——Scrap, Recovery of Zn and Cu from. (P.) 608
——Season cracking of. (S.) 847
——Tubing by centrifugal casting. Cammen 356
——Tubing, Removal of stress in. (N.).. 983
Brazilite, Reported new high explosive.. 358
Brazing and heat-treatment of brazed joints. Schaal 1121
Brazil, Manufacture of soap in 311
Breakage factors in silica brick manufacture. Jung 214
Break in crude rubber market 283
Bridge Builders and Structural Society disbands 802
Brinell hardness of cementite. (S.)..... 562
Briquets from carbonized lignite residue, Adell 207

BRIQUETTING:
——Froth concentrate from coal flotation. Ralston and Wichmann 503
——Machinery, Erection delayed by immigration laws 852
——Pure coal. (N.) 1087

BRITISH:
——Alkali Co. reduces wages 521
——Chemical companies pass dividends.. 487
——Chemical industries....53, 487, 678, 872
——Chemical prices, Effect of tariff on.. 809
——Imports of German dyestuffs 517
——Industries Fair 678
——Institute of Metals corrosion report. Comment. Cushman. Also Merica. 773
——Institution of Mechanical Engineers, report on Y alloy..... 785
——Parliament moves to protect trademarks 1140
Brittleness developed in aluminum and duralumin by stress and corrosion. Rawdon, Krynitsky and Berliner.. 154
Brittleness developed in pure lead by stress and corrosion. Rawdon, Krynitsky and Berliner 109

BRONZE:
——Aluminum, Heat-treatment of. Comment. Comstock. Also Woyski.. 388
Blue 389

BRONZE—*Continued:*
——"Leady" (N.) 1109
——Spectroscopic analysis of..... 1018
Brown University to get new chemical laboratory 279
Browne and Dow address joint meeting of N. Y. chemical societies (N.).... 948
Bucher process for the fixation of nitrogen. Thompson 124
Buffalo Engineering Society established.. 184
Building up worn metal parts by electrodeposition. Hughes. 267
Bureau of Agriculture appropriations announced 1045

BUREAU OF CHEMISTRY:
——Appropriations announced.....517, 1045
——Arranges dust explosion exhibit..... 712
——Book on dust explosions..... 1142
——Expense reduced 903
Bureau of Commerce, New head of Paper Division 227

BUREAU OF FOREIGN AND DOMESTIC COMMERCE:
——To investigate foreign chemical markets 517
——Will establish chemical commodity section 952

BUREAU OF MINES:
——Annual report for 1921..... 16
——Asks aid of industry in compiling coal storage data..... 950
——Board of censorship of industrial films 616
——Changes specifications for lubricating oils 520
——Division of war mineral supply formed for survey of mineral industries 952
——Explosibility of NH_4NO_3..... 850
——Investigations of iron blast-furnace operation 503
——Pamphlet on mercury poisoning.... 1169
——Publication on preparation and uses of tar..... 807
——Recommends standardization of mineral fillers and paving blocks.. 749
——Report on distribution of petroleum refineries in U. S. 749
——Report on mineral fillers. (N.)..... 410
——Research on oil distillation..... 784
——To investigate Georgia clays..... 843
——To study refining of Mid-Western crude oil 462
——Works on bentonite..... 971

BUREAU OF STANDARDS:
——Announces examination for junior technologist 712
——Conference on weights and measures, program 949
——Corrosion tests on chromium steels.. 1018
——Extract from Technical News Bulletin on corrosion of underground pipes 70
——Makes comparisons of national standards of mass..... 808
——Testing of rubber goods..... 27
——Work on detonation in internal combustion engines. (S.)..... 990
——Work on fuel oil viscosimeters. Herschel 1176
——Work on Pt thermocouples. Fairchild and Schmitt 158
Burton, William F., personal side of,.... 100
——Process 101

BUSINESS:
——April's progress toward better..... 857
——Conditions better..... 1094
——Conditions in January..... 233
——Cycle and foreign trade..... 905
——During February, Progress in..... 425
——Failures, Causes of..... 523
——Failures, Jan., 1921..... 283
——High spots in, during 1921..... 42
——In Chile awaits lower nitrate prices. 497
——Paper editors to meet..... 136
——Progress during March..... 664
——Side of chemical manufacturing. Wadsworth
—— I Non-technical departments..... 679
—— II Advertising 920
—— III Sales department..... 967
—— IV Credit, collection, etc. 1064
——Training of engineer, Conference on.. 472
Bus Transportation, Begins..... 183
Butterworth-Judson receivers organize... 850
Buyers' guide for British chemical industry 872

C

CADMIUM:
——Electroplating 884
——Production for 1921..... 512

CALCIUM:
——Arsenate for boll weevil control. Ambruster 1155
——As deoxidizing agent, electric iron.. 778
——Calcium carbide,
—— From limestone. (B.P.)..... 800
—— Furnaces, Söderberg electrodes for. Söderberg and Sem..... 1180
—— Held to be an inorganic chemical. 487

New Haven A.C.S. elects..... 228
N. J. Chemical Society:
——Enjoys annual outing at Princeton.. 997
——Hears Harkins on isotopes. (N.).... 806
——Hears Hill and McCready..... 374
——Hears talks on catalysis and photomicrography..... 135
——Meeting date changed..... 659
——Meeting for March. Davis and Hendrick. (N.)..... 566
——Meeting. J. F. Norris..... 952
——On record for American valuation.. 806
Newly organized company will erect large pulp and paper mill in Canada.... 807
Newly organized railroad will connect Muscle Shoals with Gulf..... 903
New point of view. Comment. Almqvist 629
Newsprint. De-inking of. (P.)..... 562
New York Market 43, 90, 138, 187, 234, 283, 330, 379, 426, 475, 523, 571, 618, 666, 714, 762, 810, 857, 906, 954, 1002, 1050, 1095, 1144, 1192, 1227.
N. Y. Section, A.C.S.:
——Discusses W, Mo and V..... 1141
——Hears papers on glues and gelatines.. 135
——Hears Norris on trend of organic research. (N.)..... 900
——Holds meeting on chemical industry in tropics. (N.)..... 518
——Joint meeting. Browne and Dow (N.)..... 948
——Program..... 229
——Symposium on glycerine and fatty acids. (N.)..... 854
Nichols award, none for 1921..... 472

NICKEL:
——Acidity of depositing solution. (N.). 878
——And alumina from Cuban iron ores. Hayward..... 201
——And iron alloy, Grain growth in. Jeffries and Archer..... 404
——Brass for brazing. Schaal..... 1123
——Catalyst for oxidation of carbon monoxide. Larson, Newton and Hawkins..... 495
——Catalyst for removal of CO in ammonia synthesis. Larson and Brooks..... 557
——Effect of, on electrolytic refining of zinc. Scholl..... 000
——For building up worn metal parts by electrodeposition. Hughes..... 267
——In Y alloy..... 785
——Lined calorimeter bomb. Ohn and Wilkin..... 695
——Steel. Flakes and woody fracture of. (N.)..... 393
——Wire, Electrical properties of. (N.). 1108
NITER:
——Consumption in sulphuric acid plant, graphic record of. Rupard..... 365
——Consumption, sulphuric acid plants. Larison..... 833
——Introduction of as mixed acid in sulphuric acid processes. Larison. 642
Nitrate sales by government..... 857
Nitration, Methods of for cellulose. Du Pont..... 12

NITRIC ACID:
——Absorption. (B. P.)..... 705
——By ammonia oxidation. (S)..... 704
—— Some economic aspects of. Taylor.. 1217
——Dilute solutions, Concentrating. Carpenter and Babor..... 443
—— Correction..... 871
——For ammonium nitrate manufacture. Symmes..... 1070
——Fume recovery. (P.)..... 798
——Retorts for supplying niter to sulphuric acid processes. Larison... 642
Nitrides, Determination of in steel. Hurum and Fay..... 218
Nitrobenzene and coal, Hydrogenation of. (S.)..... 370
Nitrogen:
——Bases of coal tar. Morgan and Soule 977
——Determination in steel. Hurum and Fay..... 218
——In oxyacetylene welds..... 365
——Problem in agriculture. White..... 163
——Production at Oppau. Tour..... 308
——Sources of for experiments on ammonia synthesis. Larson, Newton and Hawkins..... 494

NITROGEN FIXATION:
——Arc process plants may be established by Norwegian Government..... 612
——Bucher process. Thompson..... 124
——Development of processes during war. White..... 162
——German and American plants. Tour, II..... 307
——Importance to nation. White..... 164
——In Germany..... 212
——New plant in Germany..... 709
Nitroguanidine, Proposed manufacture at Muscle Shoals. Tolman..... 466
Nitro sale involves suit by aluminum company..... 1045
Non-flammable mixtures of organic solvents for vegetable-oil extraction. Sievers and McIntyre..... 603
Non-flammable mixtures of solvents. Dodge 868
Non-metallic mineral filler industry. (N.) 410
Norway, Söderberg electrode installation. Söderberg and Sem..... 1179
Norwegian Government considering establishment of state-owned arc-process nitrate plants..... 613
Notched bar testing. Holz..... 941
Notes on the chemistry of chromyl chloride. Darling..... 59
Notes on the manufacture of high-speed and tungsten steels. Weitzenkorn 504
—— Comment. Daeves..... 869

O

Oakdale explosion of ammonium nitrate. Munroe..... 538
Obituary....41, 185, 232, 280, 328, 377, 521, 568, 616, 663, 712, 760, 808, 855, 904, 952, 1048, 1093, 1142, 1190, 1225.

——Tariff schedule passed..... 1046
——Works on antimony field in Australia. 1141
Palmer would welcome investigation.... 1139
Pan-Pacific conference to foster international relations..... 1142

PAPER AND PULP:
——Association meetings expect large attendance..... 062
——Canadian Co. reorganization involves legal tangle..... 711
——Coloring, Application of direct dyes in (N.)..... 739
——Cooked by the soda process, Factors influencing yield and strength (N.)..... 755
——Cotton linters for (N.)..... 185
——De-inking of paper (P.)..... 562
——Digestor, Sugar formation in (N.)... 738
——Division of Bureau of Commerce gets new head..... 227

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis;
(N.)—Papers read at society meetings but not printed in full.

PAPER AND PULP—*Continued:*
——Drying of, Symposium at T.A.P.P.I. meeting ... 755
——Esparto, Scotch producers combine to push ... 508
——Grinders, Automatic load regulator for. Artz ... 367
——Growth of industry in Michigan ... 108
——Industries in Maine develop hydro-electric resources ... 709
——Industry, Power plant of (N.) ... 756
——Industry, Statistical study of ... 473
——Industry, Trend of ... 473
——International Paper Co. shows loss ... 857
——Making, Summer courses at Maine ... 1141
——Manufacture, Use of rubber in ... 345
——Mill operates largest electric boiler ... 1000
——Mills, Modern lighting for (N.) ... 756
——Mills, Wage decrease ... 617
——New mill will be erected in Canada. ... 807
——Production 1917 to 1921 ... 473
——Soda process, Control and recovery (N.) ... 756
——Sources of Australia, To investigate. ... 884
——Statistics on production ... 761
——Week in New York ... 616
Paper production costs ... 761
Paradichlorbenzene as spray ... 186
Pasteur to be honored ... 760
Patent bill, Substitute proposed by Howard ... 900
Patent convention with Germany:
——Chemical industries protest revival of ... 615
——Renewal delayed ... 660
——Revival favored ... 902
——Revived ... 948
Patent department, functions of. Jenks ... 396
Patent Office Relief:
——Assured ... 421
——Backed by Engineering Council ... 134
——Bill passes House ... 182
——Bill reported favorably to Senate ... 227
——Bill near final stage ... 327
——Bill passes Senate ... 374
Patents:
——And industrial research. Jenks ... 394
——Field for university. Wendt. Also answer by Hale ... 293
——Protection of inventors ... 377
——Recent Chemical and Metallurgical ... 35, 84, 225, 325, 370, 515, 562, 608, 705, 798, 849, 896, 944, 991, 1043, 1183
——Would shorten protection term of ... 609
Patent working clause:
——Proposed ... 660
——Modified ... 759
——Postponed ... 804
Paving Blocks:
——Need for standardization of ... 749
——Porosimeter used in making ... 971
Peat:
——Bogs of Maine to be exploited ... 711
——Drying ... 53
Pentosans, Furfural from. Mains ... 779
Perfume, Duty on bases ... 183
Perfumes, natural and synthetic (N.) ... 728
Perkin medal presented to William M. Burton ... 100
Permanence of steel gages ... 248
Perpetual inventory of stores discussed in Chamber of Commerce pamphlet ... 685
Personal ... 41, 87, 136, 185, 232, 279, 328, 377, 424, 472, 521, 568, 616, 663, 712, 760, 808, 855, 904, 952, 1000, 1048, 1093, 1142, 1190, 1225
Personnel, Improving efficiency of ... 617
Peru, Exports of vanadium from ... 105
Pests, extermination of by poison gas ... 787
Petroil, definition. Jenson ... 512

PETROLEUM:
——Companies, Summary of new ... 225
——Companies using fullers earth. Parmelee ... 177
——Cracking distillates by Burton process ... 101
——Cracking for gasoline (S.) ... 847
——Developments in Canada ... 902
——Distillation products, Fatty acids from ... 944
——Emulsions, Dehydrating (P.) ... 799
——Fields, delay in drilling means loss ... 688
——Fields, extent of potash deposits in. ... 300
——Field yields potash ... 903
——Hydrocarbons, Oxidizing. James ... 209
——Industry:
—— In Russia under Bolshevik régime ... 512
—— Italian ... 630
—— Problems of early. Jones ... 546
——Institute scale for reporting gravity. ... 1120
——Midwestern crude to be studied ... 462
——New strike indicates large northern field ... 998
——Nomenclature for oil-shales. Jenson. ... 509
——Oils, Physical properties of (N.) ... 735
——Production, Effect of back pressure on ... 971
——Production in Dutch East Indies ... 127
——Products, New. James ... 209
——Production, Record during March and April ... 953
——Record production of ... 282
——Refineries, Distribution of in U. S. ... 749
—— In the U. S. ... 1158
——Refinery apparatus must be more efficient as competition increases ... 784
——Refining:
—— Equipment:
—— Corrosion of (N.) ... 73b
—— Corrosion of. Matthews and Crosby ... 1119
—— In 1921 ... 522
—— Methods of concentrating sludge acid ... 1159
—— Process (P.) ... 1183
—— Recovery of gasoline from uncondensed still vapors (S.) ... 1133
—— Texas leads in ... 1112

PETROLEUM, Refining—*Continued:*
—— Thermal problems of. Comment. McAdams ... 918
—— Thermal properties of. Mekler ... 774
—— Tubular heaters. Foster ... 462
—— Use of fullers earth. Maynard and Mallory ... 1074
——Research (N.) ... 720
——Research committee, A.C.S., appointed ... 901
——Residues. Botkin ... 445
——Section, A.C.S. to become division ... 735
——Specifications ... 809
——Specifications changed ... 521
——Stills, Types of. Mekler ... 774
——Substitutes. Jones ... 546
——Testing methods published ... 1048
——Texas leads in production ... 90
——To explore new Canadian territory for ... 615
——Viscosimeters. Herschel ... 1175
——Wells in Texas as source of potash. Steiger ... 175
Phenol, Uses of. Huff ... 114
Phenol-aldehyde condensation products:
——Companies reach agreement (Redmanol, Bakelite) ... 996
——Sulphonation of for tanning agents (B. P.) ... 705
Phenols:
——Decomposition of low-temperature. Morgan and Soule ... 1026
——In low-temperature coal tars. Morgan and Soule ... 926
——Removal of from waste liquors (B. P.) ... 992
Phenylglycine-o-carboxylic acid (N.) ... 738
Philadelphia Section, A.C.S. urges national meeting in Philadelphia ... 615
Philadelphia sesquicentennial, Technical societies interested in ... 615
Phosphate rock production in 1921 ... 971

PHOSPHATES:
——Fertilizer (B. P.) ... 944
——Industrial uses of. Meckstroth ... 223
——Manufacture of. Meckstroth ... 77
——Plant to be built in Florida ... 998
——Rock deposits in South America. Wilson ... 748

PHOSPHORIC ACID:
——And phosphates, manufacture of. Meckstroth ... 77
——Industrial uses of. Meckstroth ... 223
——Manufacture of in electric furnace (N.) ... 726
——Possibility of making at Muscle Shoals. Tolman ... 466
——Titration of (N.) ... 873
Phosphorus:
——Bombs used in naval attack, photographs ... 498, 499
——In open-hearth steels (S.) ... 943

PHOTOGRAPHY:
——Exhibit to be included in Chemical Exposition ... 758
——Technical and industrial, Exhibition planned of ... 662
——Technical society will meet at luncheon ... 1091
——Technical, to be fostered by new society ... 949
Phthalic anhydride, anthraquinone from (B. P.) ... 896
Physical metallurgy at Columbia University. Thum ... 984
Piette coke oven. Prud'homme ... 794
Pigment, Novel process operated by paint company ... 422
Pigments (B. P.) ... 944
Pigments, Colloidal (B. P.) ... 225
Pine oil, Composition of. Stevens ... 629

PIPE:
——Centrifugal casting. Cammen ... 354
——Corrosion of underground ... 70
——Welding curved coils ... 34
Pitch, Uses of ... 114
Plant transportation, roadways and concrete. Montgomery ... 1169
Plastic Flow of MR. North ... 258

PLATINUM:
——Black catalysts (N.) ... 567
——Effect of on storage batteries. Gillette ... 983
——Industry of Colombia. Wilson ... 745
——Loss in weight by volatilization. Fairchild and Schmitt ... 159
——Production in 1921 ... 1024
——Production organized by Soviet ... 176
——Thermocouples, life tests of. Fairchild and Schmitt ... 158
Plauson colloid mill ... 678
Plea for reduction of freight rates by Manufacturing Chemists' Association ... 278

POLAND:
——Effect of Upper Silesian plebiscite on chemical industries ... 76
——Industrial conditions in Upper Silesia ... 260
——Prospects of steel industry ... 895
——Zinc and lead industry ... 895
Polyhalite, in Texas oil wells. Steiger ... 175
Porcelain, Electrical. Manufacture of. Jones ... 438
Porosimeter:
——For determining porosity of clays (N.) ... 488
——Used in ceramic investigation ... 971
Possibilities for commercial development of Muscle Shoals. Tolman ... 465

POTASH:
——Alsatian deposits to continue privately operated ... 711
——American in 1921 ... 282

POTASH—*Continued:*
——American now meets government standard ... 1223
——Brines, Evaporation of at Deep Springs Valley. Palmer ... 1031
——Deposits in oil fields, extent of ... 300
——Deposits of Chile. Wilson ... 748
——Domestic production in 1921 ... 784
——Duty, Farmers unite in protest ... 421
——Extraction, Edison working on ... 1136
——Extraction from leucite (P.) ... 608
——Found in new area in Texas ... 903
——From greensand. Correction. Shreve. ... 534
——German prices advanced ... 618
——German production, 1921 ... 80
——In America, Can we afford to make (N.) ... 731
——Operations resumed at Searles Lake ... 855
——Opposition to tariff schedule ... 899
——Paragraph faces fight ... 1138
——Producers ask tariff protection to give American industry a fighting chance ... 612
——Producers encouraged by tariff prospects—operations resumed ... 855
——Producers hopeful for 5-year protection ... 135
——Producers want protection ... 567
——Production costs at Searles Lake ... 613
——Production from feldspar (P.) ... 1183
——Recovery from spent oil-shale. Jones. ... 551
——Recovery from wool washing ... 271
——Rocks containing, KCl extraction (B. P.) ... 992
——Salts of Western Texas. Steiger ... 175
——Tariff rates protested ... 1046
——Western fields, Secretary of Interior urges government aid in development of ... 517
Potassium:
——Chlorate, Effect on detonating efficiency. Grotta ... 1130
——Chloride:
—— Extraction (B. P.) ... 992
—— Production from leucite (P.) ... 608
Potential demand for cosmetics in China. ... 553
Pottery manufacture in the East Liverpool district. Jones ... 346

POWER:
——Exposition to be held ... 760
——Map of Pennsylvania shows stations and lines of public utilities ... 807
——New public service map issued ... 269
——Plant for pulp and paper mills (N.) ... 756
——Plant, New, of Commonwealth-Edison ... 133
——Plants, industrial, Census of ... 928
——Project, New, for Pacific coast ... 470
——Specialty Co. heaters ... 458
——Test codes committee completes 3 codes to be discussed at A.S.M.E. meeting ... 854
Precious metal companies, Tax returns of ... 465
Precious stones, Occurrence in South America. Wilson ... 749
Preheating high-speed tools ... 593
Preliminary program announced for U. S. Chamber of Commerce meeting ... 901
Preparation of metal for microscopic examination. Campbell ... 1163
Preparation of synthetic organic chemicals at Rochester ... 76
Present status of Calvert process for alcohol from water gas ... 711
Pressed steel lineshaft hanger ... 607
Pressure containers:
——Strength of welded (S.) ... 796
——Tests on (S.) ... 797
Price fixing, Supreme Court decision. Gustin ... 685
Price lists ... 45, 92, 140, 188, 236, 285, 332, 381, 428, 477, 525, 573, 620, 667, 716, 764, 812, 859, 908, 956, 1004, 1052, 1097, 1146, 1194, 1229

PRICES:
——Of metals and chemicals ... 137
——Of portland cement ... 358
——Review of chemical, first quarter 1922 ... 665
——Wholesale in January ... 426
——Wholesale in February ... 425
Primary detonating compound (P.) ... 371
Princeton, N. J. Chemical Society's outing in ... 997
Problems of the American shale oil industry. Jones ... 546

PRODUCTION:
——Industrial, will increase in 1921 ... 474
——Of domestic graphite ... 829
——Of ethyl alcohol from acetaldehyde (P.) ... 799
——Of gasoline by cracking heavier oils (S.) ... 847
——Of gypsum in 1921 ... 971
——Of metallic magnesium. Allen ... 987
——Of phosphate rock in 1921 ... 971
——Of potassium chloride (P.) ... 608
——Of shrunk coke in electrode manufacture. Yardley ... 321
Progress in dust-explosion prevention. Price ... 1203
Progress of molding sand research work ... 663
Prohibition of oil discharge into streams issue of moderated pollution bills ... 613
Properties of single crystals of aluminum (S.) ... 514
Properties of so-called amorphous metal. Comment. Dean ... 965
Properties of some steels in hardening range (S.) ... 798
Proposed working clause in patent laws modified as result of protests ... 759
Protecting iron with paint against atmospheric corrosion (N.) ... 132
Protoplasm, Structure of (N.) ... 424
Publications New ... 143, 336, 432, 816, 864
Publicity, Manufacturers neglect. Withrow ... 972
Pug mill used for electrical porcelain. Jones ... 439

(P), (B. P.)—United States and British patents respectively; (S.)—Synopsis;
(N.)—Papers read at society meetings but not printed in full.

PULP:
——Cotton linter (N.) ... 756
——Grinders. Automatic load regulators for. Artz ... 367

——To be studied by U. S. Chamber of Commerce..... 710
Trade marks, Parliament moves to protect 1140
Traffic department. Wadsworth. (IV).... 1067
Transparent films of metal. Comment. Whitney. Also Outerbridge..... 582
Transportation in plants. Montgomery... 1169
Treaty, Effect on chemical warfare. McBride..... 351
Trend of modern organic research discussed by N. Y. section A. C. S. (N.)..... 900
Trend of production in chemical industries 1143
Trent Process:
——Oil and coal agglomerate used as plastic fuel..... 22
Trichlorethylene. Boiling range of. Sievers and McIntyre..... 603
Tropics, Chemical industry in (N.)..... 518
Truck, Drop frame factory..... 654
Truck, New gasoline-powered lift..... 942
Tuberculosis in industries, Control of. Aupperle..... 594
Tubes, Causes of rejections in boiler. Carter..... 1113
Tubing, glass, Manufacture of. Montgomery..... 789
Tubular heaters. Foster..... 461

TUNGSTEN:
——And high-speed steels. Notes on the manufacture of. Weitzenkorn 504
——Atomic disintegration of (N.)..... 567
—— Comment. Goetschius..... 676
—— Reply. Wendt..... 772
——Germination of grains. Jeffries and Archer.....408, 455
——Grain growth in compressed powder. Jeffries and Archer..... 406
——Grain structure of. Jeffries and Archer..... 403
——In the United States..... 105
——Molybdenum and vanadium discussed at N. Y. Section A.C.S..... 1141
——Pure, Mfr. of (N.)..... 1141
——Rapid determination of. Comment. Rohm..... 1060
——Refining (B. P.)..... 35
——Resources of South and Central America. Wilson..... 698
——Steels. Notes on manufacture of. —— Comment. Daeves..... 869
Turpentine:
——Borneol from (B. P.)..... 991
——Wood from stumps (N.)..... 731

U

Udylite process, cadmium plating..... 884
Uehling filter for flue gas..... 514
Ultra-clay, New concept of soils..... 744

UNEMPLOYMENT:
——Among far-western engineers..... 474
——During December..... 138
——Of engineers decreasing..... 806
——Solving some problems of..... 137
——Statistics on for 1921..... 40
Uneven fall in prices of basic commodities 137
Union College holds exhibit..... 518
United Dyewood Corporation, report..... 475

U. S. CHAMBER OF COMMERCE:
——Building dedicated..... 999
——Bureau of Foreign and Domestic Commerce will establish chemical commodity section..... 952
——National Council sentiment opposed to metric system..... 472
——On trade associations..... 372
——Pamphlet on inventory of stores.... 685
——Plans plant depreciation study..... 86
——Preliminary program May meeting.. 901
——Referendum vote shows opposition of business to bonus..... 469
——Report on coal available in case of strike..... 560
——To discuss effect of European conditions..... 807
——To study trade associations..... 710
U. S. Industrial Alcohol Co. reports deficit. 810
U. S. nitrate plants. Tour...245, 307, 359, 411
U S. production of refined primary lead in 1921..... 931
U. S. Rubber Co., annual report..... 379
Unity of recrystallization studies. Holz.. 580
Universities and industries co-operate in molding sand research work..... 662
Urea, from cyanamide (B. P.)..... 225
Utah announces fellowships in mining and metallurgy..... 807
Utilization of water power at Muscle Shoals by Haber process proposed. 659
Utrecht meeting of international chemists. 760

V

Vacuum evaporation of spent lye. Sanger. 1215
VANADIUM:
Crystal structure of. (N.)..... 1024
——Exports from Peru..... 105
——Manufacture of. (N.)..... 1141
——Resources in Latin America. Wilson. 699
Vapor luster on pottery..... 222
Various methods of hardening high-speed steel. Comment. Rockwell..... 52
Varnish company establishes museum..... 228
Varnish dipping tanks, Fire hazard at... 1220
Vegetable oil:
——Extraction, non-flammable mixtures of organic solvents for. Sievers and McIntyre..... 603
——Bleaching with fullers earth. Maynard and Mallory..... 1075
Ventilation of vehicular tunnels. (N.).. 997
Vicronic metal..... 58
Virginia-Carolina bond issue..... 1002
Viscose:
——Filaments, Recovery of salts. (B. P.) 225
——Precipitating bath. (B. P.)..... 226
——Threads wound in solution of ammonium salt. (B. P.)..... 515
Viscosimeters, Fuel oil. Herschel..... 1175
Viscosity measurement. (N.)..... 736

W

Wage comparisons in chemical and allied industries..... 569
War Department surplus nitrate, Do not buy..... 802
War gases to be used for extermination of pests..... 787
War minerals division of Bureau of Mines formed..... 952
Warner-Klipstein merger reports unfounded..... 902
Washington Chemical Society elects..... 184

WATER:
——Analysis:
—— Bibliography. Buswell and Edwards 829
—— Value of pH determination in (N.) 740
——Corrosive action in producer-gas cooling system. Jackson..... 61
——Pollution:
—— Bills would prohibit oil discharge in streams..... 613
—— Conference to be called..... 1224
—— Fish commission warns against drastic prevention measures.... 568
—— International conference on proposed..... 376
—— Resolution passes House..... 1141
——Power committee of F.A.E.S..... 227
——Purification, Removal of iron. (N.) 740
——Residual alum in filtered. Buswell and Edwards..... 827
——Softening by lime-soda ash method. (N.)..... 740
——Supply for tire plant from air lift. Stone..... 606
——Power resources of the world..... 30
——Testing methods described..... 710
Weighted index, Announcing..... 88
Weights and measures, Annual conference on, program..... 949

WELDING:
——Electric, Strength and efficiency of (S.)..... 797
——Pressure containers. (S.)..... 796
——Curved pipe coils of a glucose tank.. 34

WELDING—*Continued:*
——Automatic electric..... 872
Welds, Nitrogen in..... 365
Western Reserve University offers summer courses in chemistry..... 805
Westinghouse automatic load regulator for pulp grinder. Artz..... 367
Westinghouse, George, Life of. Comment McDonald..... 964
West Virginia to have new laboratory... 326
Wheels, Thermal stresses in car..... 269
When does a currency collapse?..... 186
When does an employment contract terminate?
——Comment:
—— Gustin..... 341
—— Landis..... 484

Forgetting Those Things Which Are Behind

GLANCING over our editorial salutation of a year ago in which we attempted to portray an optimistic view of the year that has just passed, we are struck with the fact that in many respects the promise has not been performed. Tariff legislation, which was then considered to be of primary importance in the revival of business, still awaits the intelligent attention of Congress. Revenue legislation, which was also a factor in the expected return to normal business conditions, was enacted too late in the year to relieve materially the burden under which business was already staggering. The situation with regard to foreign exchange has not been improved, with its consequent prohibition on international trade. In short, it would seem as though the skyrocket career of 1920 has had its inevitable sequel in the descending stick throughout 1921.

On the other hand, the feeling of optimism and confidence with which we approached 1921 has not been dissipated, although the events which subsequently supported and justified it were not apparent at the beginning. There has been increasing evidence of willingness on the part of business men to accept fundamental economic principles and to ignore artificial panaceas and nostrums in their attempts to revive business. This influence has been felt in Congress and is undoubtedly the principal reason why a high tariff bill has not been passed, as might have been expected under existing political conditions. Economic sanity has prevailed over political expediency.

The tariff is but one item in which there has been evident willingness to take the broad international rather than the narrow national view. The Conference on Limitation of Armament is another. Its success has been such that already there is a demand for a second international conference to solve some of the fundamental economic problems that now vitally affect the business of all nations. Add to this the fact that through Federated American Engineering Societies attention has been forcibly directed to the necessity for eliminating waste in industry, and we have a trio of influences that augur well for the future and serve to relieve the pessimism which otherwise might prevail in a cursory review of 1921.

But we are more concerned with the future than with the past. CHEMICAL & METALLURGICAL ENGINEERING has confidence in the ultimate adjustment of our present economic and financial dislocation. We conceive it to be our duty to contribute to that readjustment by rendering sevrice that will enable American industry to attain a higher degree of efficiency than it has ever known. To this end we have determined to expand rather than contract our editorial activities. Two new engineers will be added to the staff and one of the present members will go to Europe for at least six months. This will enable us to consummate plans that have long been cherished and which we believe will react greatly to the benefit of the chemical and related industries.

Two new features will be incorporated in the magazine: One relating to the economics of the chemical industry and the other to mechanical engineering in industrial processes. Qualified editors will devote their time to these activities. A survey of the economic and commercial factors that influence trade in chemicals and related commodities will appear each week, and an effort will be made to interpret financial and trade movements in their relation to the chemical industry. A more detailed statement of our plans will be found elsewhere in this issue in the department devoted to the subject.

The decision to pay more attention to the mechanics of industrial processes and methods of handling materials arises from a desire to supplement our excellent contributions on technology, industrial and scientific research with more articles from the field giving practical details of operation. A mechanical engineer experienced in construction and operation of chemical plants will be in charge of the work.

Sending an editor to Europe for six months should have many practical consequences of great benefit to our readers and advertisers. Through him we shall hope to reflect industrial conditions in Germany, Belgium and France and interpret them for the information and guidance of American manufacturers and consumers. Our future is inevitably bound up with that of Europe and it will only be through intelligent comprehension of conditions in the principal European countries as well as in our own that our industrial leaders will be able to chart their future business course. It will be our purpose to render some small service to this end by reporting at first hand conditions as our representative finds them.

Crumbs of Wisdom Out of the East

AN AMERICAN man of affairs was lately talking to a Chinese gentleman of the old school. The latter was robed in beautiful silk; he was a thoughtful person, but unconvinced that whatever comes out of the West is good for the East. The American was describing the Twentieth Century Limited, and explaining how in 20 hours he had frequently traveled from New York to Chicago, a distance of nearly a thousand miles.

"And when you arrived at Chicago, what did you do?" asked the gentleman of the East. The American could not remember.

Here is a point in philosophy that it may do us no harm to consider. The detached Oriental does not want to go from New York to Chicago except for a purpose, and if possible he would prefer to send some one else on the journey than to make it himself. This is with

no reflection on Chicago or the railway company and its facilities. If he were comfortably settled in Chicago, he would have the same objection to rushing to New York. He is rather more advanced than we are in the art of finding out what he wants and then in proceeding to enjoy it. Another of his merits is that he is less disposed than we are to run away from himself. Very often when we say "I've got no time to bother about" this or that or t'other thing we are seeking another occupation to avoid responsibilities and decisions that we are afraid to meet. What we Americans need to have drilled into us by some kindly mentor is to keep our eyes a little more firmly fixed on the goal, and to make less fuss about the incidents of our travel thither.

H. G. WELLS refers somewhere to a class of people he calls the "Godsakers"; meaning those who are constantly exclaiming, "For GOD'S sake let's do something!" —without knowing what to do. We know very well how futile misdirected efforts are in chemical experiment. This is the very basis of research. But it holds true in nearly every walk of life. The nerve-racking haste to do indefinite things is what makes many of us old before our time, and spoils us for our old age as well.

The Chinese gentleman might give us profitable instruction in other respects. Politics are indeed in a bad way over there, but then the Chinese people do not lean on politics as we do to manage everything they can't manage themselves. We want to be let alone in our own business, but a considerable number of us seem to want the government to step in and regulate the other fellow to our profit. The Chinese is singularly free from such aspirations, for good and sufficient reasons.

Again, he is very loath to go to law. If he has differences with his neighbor, they take their quarrel to two or three of the old men of the community, who decide the matter for them with at least as great a measure of wisdom as a judge can do with several scrapping lawyers to handle. This provides an economical use for their old men, who are not cast aside as "back numbers" in the process. The Chinese are an ancient people with vast experience, and some of the things they know and which we neglect have the merit of truth.

Putting the Cart Before the Horse

THE young man failed to pass his examination in freshman chemistry. Some of us do not take incidents of that sort very seriously, but the freshman in question was one of a long line of persons eminent in scholarship. Cousins, father, uncles, first cousins once removed, grandfather and great-grandfather, all had been in the habit of taking honors. In the young man's case other marks were high, but chemistry was a failure. The father discussed the subject with a professional friend who is also of a scholarly turn of mind. And the sequel was a luncheon engagement between the latter gentleman and the boy.

"The trouble is," said the young man, "I don't believe what they say is so. There's this oxidation business, for instance, that sometimes means one thing and sometimes another. I am told to believe a whole lot of things that may be true and again they may not; but I can't see it. I am interested in what I can see or understand, but I do not believe the professor himself understands the line of talk that he passes out to us. If he does, why doesn't he explain it? The thing does not seem reasonable to me!"

"I am glad," said the older man, "to find someone with a mind like my own. Chemistry really is a subject of immense interest, but from what you have told me they have not been trying to teach you chemistry; they have offered rather a sort of chemical theology. That you resent the teaching of whilom fancies about various chemical reactions indicates to me your good judgment, for you may be sure that in five or ten years from now many of these very fancies will be discarded." The ensuing conversation led into the field of descriptive chemistry, and here the young man immediately found his curiosity excited.

We know very well that we need philosophy all the time; we need to arouse our curiosity as to why things happen, and to keep this constantly alive, in all scientific work. But we venture to express the fear that there is a great deal of unilluminated teaching of the philosophy of chemistry, and this in such a manner as to kill the subject for the student.

Suppose we were discussing persons, and in response to your inquiry about JOHN DOE we were to send you his genealogical chart. It would not give you the information desired. We do not know enough about anybody alive to prepare a complete genealogical chart, and we don't know enough about heredity to compute a man's character, even if such information were available. It is so about things. We want to know why reactions take place, but this desire will remain inert unless our interest is aroused in the reactions themselves.

The way to get at chemistry is to see what it does, to watch its workings, to get imbued with the romance of it. Then students of a philosophical turn of mind will want to know the reasons why. Others will never get beyond the romance of it, because they lack the gift of philosophical curiosity. Here are, let us say, a hundred young men, taking freshman chemistry because it is in the curriculum. Only a few will follow it much further. The others will be interested or not; will get a sense of the subject in their minds so that they will know how to learn what they may want to understand later, according as we set the table for them. It should be a handsome display of what chemistry does; a descriptive display, to open the portals of their minds. Speculations as to the reasons why things happen should come later.

Why spoil the subject for fresh young minds by something that is very like theological dispute, when there is such a great store of beautiful things to show them? It looks to us as though some teachers of elementary chemistry are on the wrong tack.

Psychology in the Selection of Workers

ARE WE NOT neglecting the craftsman? In days gone by he was an important person, but in latter years it seems as though everything, inventors, employers and even his own fellows, had combined to obliterate him. The inventor in devising machinery has tried to get along as much as possible without him and to turn him, when and where he is needed, from a fashioner into a feeder. The employer would naturally rather pay feeders' wages than fashioners' and he has pulled in the same direction. The craftsman's unions, in seeking strength, have taken in the incompetents, and then have been compelled to demand that the work be made simple and easy enough for their incompetents to perform. The multiplicity of unions has also over-

lapped, and the result of this has been to restrict the variety of work that each member may perform.

At the present moment we are not discussing wages or living conditions, save as these are found in work. In this respect we venture the belief that variety is needed for human development. Psychologists have not yet achieved the art of making mental tests to determine exactly and fully how and in what direction a man may develop, but they have gone much further than most of us think. For instance, in one great manufacturing establishment that annually engages a considerable number of graduate engineers, it formerly required from one to two years to determine whither the young man should be guided: either into design, manufacture or sales engineering. Now by the aid of earnest study by trained psychologists they know as much of the native talent and capacity of the young men so taken on at the end of six weeks as they formerly did at the end of two years. Several life insurance companies now select their agents with the help of competent psychological study with a small fraction of the mistakes they formerly made in their appointments. A number of department stores, after long and serious study by competent and experienced psychologists of the problem of selection and administration of their personnel, have developed methods that result in such marked improvements in service that no less than 60 per cent of their charge customers have noted the difference.

Now if among such human material as seeks employment in department stores, the major portion of whom have not got beyond the eighth grade of grammar school, proper methods of selection and training make a great difference in the capacity of the sales forces, is it not time that the rest of us, who have other work to do than to sell tidies and needles and pins and yards of cloth, should begin to look over our staffs of workers?

Every one of us needs looking after, no matter what his position in an organization may be. If we are at the top, the chances are that the family doctor rules us with a far severer rod than the dispensary physician does if we run an elevator. In conferring lately with the head physician of a great college of technology we discovered that the young men of eighteen to twenty-two are really as tender as girls and that absurd little causes will often ruin the career of a young man unless there is an intelligent helper at hand to advise and reason with him and to guide him into ways that are wholesome for him.

How about the vast crowd of men, generically classed as "labor," with nobody to look after them, and of whom a disproportionate lot of splendid fellows are going to ruin and collapse for the reason that nobody does look after them? The union cannot give them mental tests and physical examinations, and nobody else does, and so thousands and thousands are eating their hearts out from some—to them—poisonous idea, or are making for tragedy with only an enlarged thyroid as the signal, and with nobody to know or care. If big department stores find it even profitable from the standpoint of business to engage psychologists in providing for the selection and administration of their forces of necktie men and passementerie women wouldn't it probably pay the rest of us to remember that all our employees are in our business family, and that in both selection and administration we should seek the best? And how do we know that in our own vanity the best is to be found? It would be abundantly worth while for a great many of us to look into the subject.

Wage Disputes In the Coal Industry

THE United States Geological Survey issues, without comment, a report on "strikes" in the coal industry in the twenty-one years 1899 to 1919 inclusive. As will be indicated later, it is possible that the subject matter of the statistics might better be referred to as "wage disputes" than as "strikes."

The showing indicates conclusively that something is radically wrong somewhere. This is distinctly the way not to do it. There is no statement of the total number of men engaged in the industry, and for that reason alone no direct comparison could be made, while the strike statistics are not complete, because they are compiled solely from reports of operators who produced in 1919.

As to the number of men involved in strikes or wage disputes, the latest year in the presentation, 1919, shows the greatest number, with 446,436 men losing a total of 15,693,567 man-days, equal to an average of 35 days per man, while 1910 shows the largest number of man-days lost, 19,250,524, or an average of 88 days per man for the 218,493 men involved.

Of the twenty-one years there were five in which more than 200,000 men were on strike at one time or another. A better appreciation of the importance to society of loss of working time is furnished by striking an average of the twenty-one years which shows approximately 6,000,000 man-days lost per year in the period, equal to 25 working days each for 240,000 men. In other words, the incomplete record of wage disputes in coal mining for more than two decades shows an equivalent of 240,000 workers being idle for one whole month each year.

Some of the twenty-one years showed much more lost time than others. In an effort to see whether the strikes had any connection with business conditions, we divided the years into good years and bad years commercially, using the production and price of pig iron as the criterion. The division made ten of the years bad and eleven good, but the ten years showing the greater amount of lost time fell in five good and five bad years, while the ten years of less lost time had the same incidence. Thus the strikes or disputes were not produced by good times or by bad times. Then another basis of scrutiny was taken, this showing that of the ten years of greater loss of time nine years were even-numbered years and only one, 1919, was an odd-numbered year. This was quite intelligible. For a long time past the bituminous wage scale has been biennial, the settlement falling in the even-numbered years. The exception, 1919, was a year in which men went on strike, claiming that the scale was a war-time scale and should not bind them since the war was over.

Thus it appears that the term "strike" is quite broadly applied. The time seems to have been lost chiefly during disputes as to the new scale. The customary procedure has been for the operators and the United Mine Workers to fail to agree prior to the April 1 of the even-numbered year on which the old scale expires. Then there is a cessation of mining. stocks of coal are exhausted, the market price of coal advances, and an agreement is reached. Somebody pays for the lost time, which incomplete statistics set at an average of one month a year for 240,000 men during twenty-one years. Not a few men have lately concluded that in the last analysis it is the general public that pays for this lost time.

Readers' Views and Comments

Wanted: Jingles of Science

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am endeavoring to collect verses of a more or less humorous nature, whose subject matter relates to the sciences, with the intention of publishing an anthology of such poetry, under the title "Jingles of Science." It has occurred to me that there may be a large amount of such poetry filed away by some of the great number of chemists, physicists, engineers and other scientific men of the country, which at the present time is quite unavailable to me, by reason of its non-publication. Will you kindly grant me space for this appeal to your readers to send me copies of such verses as are available to them, and which, in their opinion, are worthy of publication? Whenever possible, I should like to have the name of the author or authors accompany each contribution. Any verses, grave or gay, referring to any of the sciences, sent to me at 7 St. Paul St., Cambridge, Mass., will be sincerely appreciated and duly acknowledged. CHARLES E. RUBY.

Cambridge, Mass.

Pitiable Plight of Russian Scientists

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your Oct. 26 issue a very noble appeal was printed, urging American scientific men to lend a helping hand to those isolated and starving Russian scientists who still remain within the boundaries of the former state of Russia. As I am a Russian, I can most deeply appreciate the high motives of this appeal and urge that those of means might find some feasible way to help. But while I continually remember those brave men who are carrying on scientific research under incredible conditions of hardship, I make bold to raise my voice to help those who could not bear life in Soviet Russia and left the country with no well-defined aims or definite plans and without the means of leading a life such as would befit a man of culture.

Over two hundred Russians, people of brains and culture, who had followed the national armies of Denikin, Kolchak and Wrangel have met with this hard experience. You can meet Russian professors on the remote islands around Constantinople, you can see them working as clerks and laborers in the railroad depots of the Slavonic states, you can observe them in Egypt, in Greece, interned in the camps erected for war prisoners.

Many of them are with us no longer. Before me lies a long list (published officially by the Bureau of Russian Scientists' Society in Prague, October, 1921) which tells of man after man who found his peaceful rest.

Those dead have laid down their lives that their brothers might live. But these who remain alive are in conditions which even my national pride permits me to call pitiful. Many are separated from their families, deprived of everything but the right to breathe.

Here is not the place to mention how and where they earn their daily bread. Sometimes they do not earn it —because they are weak and ill and downhearted. But always they support their lot in uncomplaining silence. For them I raise my voice. They are within reach. For them so much can be done. Not in the way of charity, but in the way of giving them a chance to work, to continue their researches which have elevated the name of Russian scientists so high and which in the past belonged not to Russia alone, but to all the civilized world.

Shall the world forget them now in the time of their need? Shall they pass out of our sight after all they have done for the world because their colleagues abroad did not proffer them aid?

Should any one desire to receive full information about the non-partisan Bureau of Russian Scientists the writer would be only too glad to give all the information at his command. VSEVOLOD N. KRIVOBOK.

Dept. of Metallurgy,
Harvard University,
Cambridge, Mass.

Explosion of Agitator Charged With Naphtha

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the Nov. 23 issue of your journal, W. H. Pape inquires about the cause of an explosion in an agitator which had just been charged with naphtha. It is a well known fact that oils of the nature of naphtha become charged with static electricity while being pumped through pipe lines, especially lines of small diameter. If this charge is not drained off through a ground wire, there is danger of a spark being caused by the discharge of the electrical charge contained in the naphtha. This is probably what occurred in the case he mentioned, the spark exploding the explosive mixture of naphtha and air above the liquid naphtha in the agitator. I would suggest that the pump lines to the agitator and the agitator itself be well grounded.

Wilson, Pa. WALDEMAR VERNET.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Replying to the article of W. H. Pape on naphtha explosion in your issue of Nov. 23, I recall a similar case which came under my observation about 10 years ago. In that case the agitator was on a concrete foundation, the electric wires were in conduit, the acid, lye and air lines were bonded to the agitator and the charging line was connected to the bottom of the agitator. A batch of naphtha had been pumped up, and the line was being blown out with air when the naphtha exploded.

Experiments showed that the naphtha could not be ignited by blowing air through it—that is, by an overhead line. Then an iron line that had been filled with naphtha, to represent the agitator conditions, was tried. No results were obtained until the experiment was repeated on a damp, cloudy day, when the liquid at the end of the line ignited. This could be repeated under similar atmospheric conditions.

The conclusions were drawn that the explosion was caused by static electricity and the practice of blowing light liquid pumping lines was discontinued. Since then no such fires have developed. The conditions in the case mentioned may have been similar. I. L. KLEIN.

Rossford, Ohio.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, Dec. 4, 1921.

NOVEMBER was a month of uneasiness for those engaged in the chemical industries, as a proposed general reduction in wages threatened a strike of 200,000 workmen. However, representatives of both sides got together and owing to the fact that there was a large number of unemployed the workers in Lombardy, Liguria and Piedmont were induced to accept a reduction of 1.65 lire from Nov. 1 to the end of February. This agreement has not yet been accepted by workers in other portions of Italy.

The demand for chemicals continued good and many reductions in price were avoided owing to the fact that Germany had prohibited the exportation of goods unless they had been contracted for in terms of Italian lire. This put an end to the speculation on the rise or fall of the German mark and increased the opportunities of other countries to do business, which were taken advantage of by France, England and the United States.

ITALIAN FERTILIZERS

The excessively dry weather of the fall months and the freezing weather that followed precluded the possibility of the usual rainfalls and discouraged the agriculturists from using fertilizers of all sorts. This was a serious matter for those interested in the manufacture and sale of such products, as they were left with stocks unsold and faced a fall in price. The latter is very probable, as measures have been introduced in Parliament aimed at forcing a reduction in prices, to encourage greater cultivation of the soil.

ITALIAN CHEMICALS

To encourage the manufacture of chemicals the customs officials have been authorized to waive the export prohibition on toluene, dinitrotoluene, lactose, chlorate of potash, tanning extracts, sulphate of copper and potash salts (excepting those required for agriculture). This was caused by the great success in the exportation of chlorate of potash, which amounted in the first 6 months of this year to 1,058 tons, 1,052 tons being destined to England. These exports were made after supplying the home market, only about half a ton being imported in this period. In the first 6 months of 1920 24 tons was imported and in the corresponding period of 1919 102 tons. Exportations of sulphate of copper also were very fair during this period, reaching 2,476 tons, against 4,116 and 800 tons in the corresponding period of 1920 and 1919 respectively. This product was distributed this year principally as follows: 1,190 tons to France, 358 to Jugoslavia, 11½ to Portugal and 700 to Rumania. Imports of sulphate of copper in this period reached only 598 tons, against 791 in 1920 and 35 in 1919. Of that imported this year 401 tons came from England and 57½ tons from the United States.

ITALIAN PURE ACETIC ACID

With the view of encouraging the greater use of pure acetic acid and increasing its production it has been decreed that manufacturers whose product is destined for industrial use will not be subject to the tax of 200 lire per annum which has been imposed on those manufacturers whose product is destined to be used for pharmaceutical or laboratory purposes. The imports of pure acetic acid of all concentrations during the first 6 months of this year were 109 tons, against 271 tons in the first half of 1920 and 85½ tons in 1919. Exports in the same period were 154½ tons in 1921, 110 tons in 1920 and 47 tons in 1919.

LIMITATION OF WORKING DAYS

The dry weather in November caused a scarcity of water power, consequently a limitation was placed on the operation of many manufactories, which were ordered closed for one, two or more days a week. This often interrupted their manufacturing operations and caused no end of trouble and loss. These conditions led the government to study a project for direct control of all hydro-electric plants in the hope of obtaining greater use than at present and of eliminating waste by better distribution of power. In the meantime decrees were issued aimed to increase the efficiency of plants producing electricity by other means.

ITALIAN SUGAR PRODUCTION

As the country produces scarcely enough sugar to satisfy the home demands, the government has issued new regulations regarding its importation, subject to the judgment of the Minister of Finances. Although the consortium arranged at Turin for the distribution of sugar has been eliminated and commerce in this article is now free, the government fixes from time to time the wholesale price.

Imports of sugar of first quality were large during the first half of this year, reaching 66,151 tons, against 5,146 tons in 1920 and 30,106 tons in 1919 during the corresponding period. Of this year's imports, 12,545 tons came from the United States, 6,103 from Belgium, 3,331 from France, 131 from Japan, 36,373 from the Dutch East Indies, 33 from Egypt, 2,149 from Brazil and 3,848 from Cuba.

HYDRO-ELECTRIC DEVELOPMENTS

It has been proposed to transport to Sicily a portion of the electric energy produced on the high plain of Sila, thus placing 50,000 kw. at the disposal of the island. It is proposed to erect stations at Cotrone, in the Province of Catanzaro, and carry the current on strong copper cable across the Straits of Messina to Catania, Caltanisetta and Palermo, a distance of 300 km. The Lys torrent, that descends directly from Mount Rosa to the River Dora, can furnish power for the four stations of Gressoney-Trinité, Chemonal, Gaby and Pont St. Martin. A fifth station is planned to utilize the waters of the Paconella, an effluent of the Lys. This station and that of Trinité would function only in winter, but the others could be used during the entire year.

The electric railway from Trofarello to Ronco will soon be completed, so that it will be possible to travel by electricity from Genoa to Turin. Other lines being electrified are the Ronco-Arquata-Tortona, the Turin-Novi, the Voghera-Bivio-Bormida and the Genoa-Ovada-Alessandria. It is hoped to finish soon the electrification of the Rome-Tivoli and Rome-Anzio-Nettuno lines, after which work for the service of express trains between Rome and Naples will be pushed. So by the beginning of 1923 it is expected that 500 km. of railways will be electrified, making the total in Italy 1,370 km.

As it takes from 18 to 21 months to construct an electric locomotive, the state railways has voted to order 120 at an expense of 169,000,000 lire. Some of these will be used on the lines now in operation and the remainder will be put on the new lines.

The Relations of the Iron and Steel Industry to the Chemical Industry*

The Steel Industry, an Important Consumer of Chemicals, Supplies Many of the Basic Materials for the Chemical Industry and With It Furnishes Our Chief Means of Defense as Well as Our Peace-Time Tools for Material Progress

By JAMES M. CAMP
Director, Bureau of Technical Instruction, Carnegie Steel Co.

CLASSIFIED according to their direct relations to our natural resources and with respect to their dependence for raw materials, our industries are basic or subsidiary, according to the way they are grouped, and dependent. The basic industries are those engaged in the production, or creation, of raw materials by life processes, such as farming; or in the extraction of raw materials from the earth, such as mining or oil and gas-well drilling; or in the conversion of natural potential energy into useful forms, such as our hydro-electric plants. But these industries must be supplemented by a number of others, which, although they are directly dependent upon these basic industries for raw materials and mechanical power, are so intimately related to the former by reason of their being engaged in converting and adapting certain raw materials for use that they must be accepted as co-ordinate to these basic industries and also co-ordinate to one another.

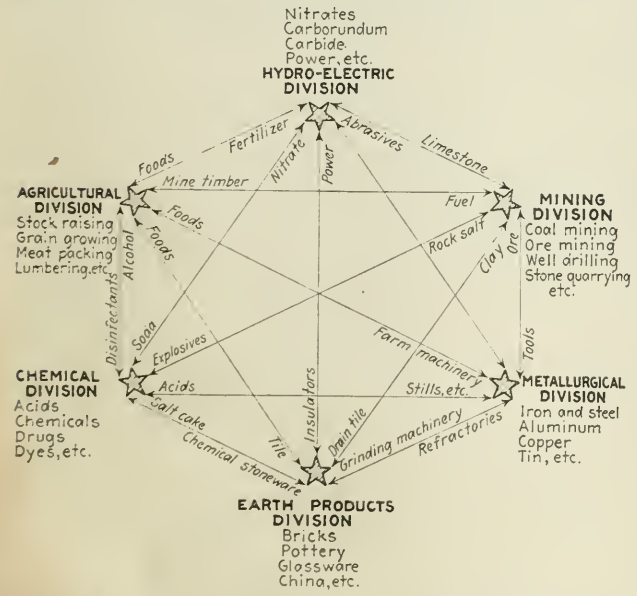

DIAGRAM SHOWING RELATIONSHIP OF THE SUBSIDIARY DIVISIONS OF INDUSTRY TO ONE ANOTHER

Hence, all these closely related industries are to be looked upon as being subsidiaries to our industrial life as a whole.

To explain more fully what we mean to imply by this use of the term "subsidiary" it is necessary to point out that we apply this designation to groups of closely related industries rather than to any specific activity. Thus farming, for example, is really a class term, for under it are included such occupations as gardening, cattle raising, fruit growing and the growing of grain, also the sciences that relate to these arts. From this standpoint we are able to separate our industrial life into a number of divisions, which we shall term the subsidiary divisions of industry. For want of better names, we designate the basic subsidiary division devoted to the production of raw materials by life processes as the agricultural division; that devoted to the extracting of raw materials from the earth as the mining and well-drilling division; and that devoted to the transforming of natural energy as the hydro-electric division. As to the dependent subsidiaries, we call that one devoted to the separation and refining of the metals the metallurgical division; the one devoted to the preparation of refractories, bricks, all clay products, as well as glassware, etc., the earth-products division; and that devoted to the production of chemical compounds, the non-metallic elements and certain of the rare metals, the chemical division. Some of you may think of other industries that should possibly be included as another division, but we believe that any of our industries can be placed under one or another of these divisions.

Interdependence of the Major Divisions of Industry

One of the things we wish to emphasize now is the close relation and interdependence of all these grand divisions of industry. So we would call your attention to the accompanying diagram, which will both demonstrate and vividly illustrate the point we wish to make. This diagram shows that these subsidiary divisions of industry are closely connected and related to one another because they are dependent upon one another for necessary raw materials and supplies, and are each made up of a number of related industries, so important that they are usually spoken of as being, themselves, the basic industries. Each of these industries is accompanied by a list of dependent industries so long that it was found impracticable to show them on this diagram. It is such a subsidiary division of industry, not a small branch of industry nor yet one of the dependent industries, that we have in mind when we refer to our chemical industry. It consists of the chemical industry proper and a great number of dependent industries, which, though they are not engaged primarily in the production of chemicals as such, produce articles of a chemical nature or by chemical processes, or articles that depend mainly upon chemicals. The chemical industry proper has, itself, three branches, which are known as the chemical section, the acid section and the coal-tar section.

Referring to the other part of our theme, we see in

*Paper read before the American Iron and Steel Institute, at New York, Nov. 18, 1921.

our country today a single branch of the subsidiary metallurgical division developed to such a high state of efficiency and on that account occupying such a high position commercially that it casts a shadow over the importance of even the subsidiary divisions. Such an industry is the steel industry. And here lies great danger for us, in that we may be led to attach too much importance to one industry or one division of industry and not enough to the others. Trying to decide which of these grand divisions of industry is the more important is like trying to decide which wheel of an automobile is most important, for they form the vehicle upon which our civilization is riding toward that goal set up for it from the beginning, when man was commissioned to replenish the earth and subdue it.

As the most important branch of the metallurgical division of industry, the steel industry cannot escape certain relations with the chemical industry, and it is interesting to note that these relations, both direct and indirect, are to an unusual extent interdependent. This interdependence is most vividly set forth when we consider these two industries from the standpoint of being consumers of each other's products.

Steel Industry Consumes One-Fifth of Our Sulphuric Acid

In reviewing the chemical products consumed by the steel industry, we find that sulphuric acid heads the list both as to quantity and importance. Statistics showing the quantity of this acid consumed by the whole steel industry of this country have never been compiled. We do know, however, that during the year 1920 the United States Steel Corporation used approximately 280,400 net tons, all of which was concentrated to give, on an average, a gravity test of 60 deg. Bé. This fact leads us to the confident belief that our steel industries as a whole must have consumed last year at least 600,000 net tons of this acid, expressed on the standard gravity basis of 50 deg. Bé. To make a striking comparison, the acid consumed during the year 1919 by the Steel Corporation alone amounted to almost 10 per cent of the total quantity of this acid reported by the Census Bureau as having been made in this country that year.

Of this acid used by us, nearly one-half finally went into the manufacture of ammonium and iron sulphates and thus represented a recoverable outlay, but the remainder represented an actual consumption, from which there was no such recovery of acid or any other direct tangible return for the outlay. As to the direct purposes to which we put the acid, not used in the manufacture of ammonium sulphate, a small portion was used in washing benzene and other homologous compounds produced by byproduct coke plants, a smaller portion was consumed in making chemical analyses, and the remainder was employed for pickling. The pickling process consists in immersing the steel in a warm dilute solution of the acid, and has for its purpose the removal of scale from the surface preparatory to tinning, galvanizing, cold rolling, cold drawing or chipping.

Concerning the necessity for pickling, this operation is absolutely essential in the manufacture of steel wire, of tin and terne plate, of galvanized sheets and tubes, of cold-drawn seamless tubing, and of all sheets requiring a highly finished and polished surface; and, as a means of revealing surface defects in billets and blooms, it is a great aid in the manufacture of high-grade steel, such as that required for forged and heat-treated articles. Other agents could be used for some of these cases, but the cheapness, chemical activity and high volatilization temperature of sulphuric acid make it the most satisfactory reagent that can be employed for this purpose.

The next items in point of quantity consumed by our corporation during the year 1920 were muriatic, or hydrochloric, acid and sulphur itself. Of the 10,200 net tons of the former consumed, some was used for pickling in processes where sulphuric acid is not suited to the conditions, such as the final pickling in galvanizing; some was consumed in our chemical laboratories, where it is used in practically every analysis made; some was neutralized with zinc to form part of the flux used in the manufacture of tin and terne plate; and a small portion was applied to various other purposes too numerous to mention here. The greater portion of the 22,000 net tons of sulphur used by us was consumed in the manufacture of sulphuric acid, which we also make as a byproduct in zinc smelting, but a considerable portion was employed in the manufacture of certain grades of steel, in the galvanizing of sheets and in the erection of acid-proof water-tight brick tanks.

The fourth and fifth items next in importance are salammoniac, or ammonium chloride, and soda. During the year 1920 our corporation required almost 7,500,000 lb. of salammoniac and a little more than 1,120,000 lb. of soda, most of which was in the form of the hydroxide, commonly known as caustic soda, and the remainder in the form of the carbonate, or soda ash. The salammoniac was used chiefly as a flux in the application of tin, terne and zinc coatings, but a small quantity was consumed in the laboratories and shops, where it is indispensable in some work. With the exception of small amounts used in our laboratories and for cleaning purposes the soda was employed in our plants for the neutralization of acids and corroding compounds, such as in the washing of benzene products and the softening of water for boiler use. Its effectiveness and the importance of its use for these purposes are matters that need not be elaborated upon nor emphasized here.

Other Chemical Requirements

Other items that may be of interest to certain organic chemists are the 6,000,000 lb. of palm oil used in the tin-plate plants of the corporation during 1920, the 63,477,000 gal. of fuel oil consumed, and the 3,264,000 gal. of straw oil required for the absorption of benzene and its homologs from our coke-oven gas. Tar oils may be substituted for the straw oil, but no satisfactory substitute for the palm oil has yet been found, though such a substitute has been diligently sought.

A small item is nitric acid, of which we consumed nearly 6,000 lb. in 1920. The use of this acid is restricted to laboratory purposes almost exclusively. During the same year our requirements for the nitrate of soda called for more than 3,500,000 lb. of this salt, most of which was employed in the manufacture of sulphuric acid.

Next comes a long list of chemical articles for which we have no data whatever as to the quantities consumed by the steel industry. Their importance, however, is apparent as soon as they are named or the uses to which they are applied are indicated. This list includes the various chemicals used in our laboratories for analytical purposes, and such substances as lubricants, soaps, salt, carborundum and compressed oxygen. From 1,000 to

1,200 lb. of elementary phosphorus is also consumed in the preparation of phosphor bronzes for use by the steel manufacturers.

The Chemist as a Prospective Customer

Not only are the iron and steel industries large consumers of chemicals, hence good customers of the chemists, but the chemical industries are likewise large consumers of iron and steel. We have been unable to obtain statistics as to the tonnage of iron and steel used by our chemists, but, judging from our knowledge of these industries, we know it must be large. The chemists deal largely with matter in the liquid and gaseous states, hence their apparatus consists of such vessels as stills, retorts, vacuum driers, pipes, tanks and various other containers, many of which are made of iron or steel entirely, while the remainder require these materials in their construction. They have need of much steel in the form of plates and sheets for vessels, ranging from tin cans to tank cars, in which to transport and market their materials. They employ much machinery, such as fans, rolls, pumps, presses, crushers, disintegrators and centrifugal machines, and, of course, require engines and motors to operate these machines. They require steel for their buildings, which usually must be fireproof; in 1919 there were more than 1,300 establishments producing chemicals, 811 of which were devoted exclusively to the chemical industry proper.

Some Waste Products of the Steel Industry

But it is in the sense of a prospective customer that the steel industry should show the keenest interest in the chemical industry, for the former has, to a considerable extent, gradually worked itself into the position of a producer of certain chemicals and raw materials for the latter industries. Thus during the war the scarcity and consequent high price of potash brought about the installation of apparatus for the recovery of this product from the dust in blast-furnace flue gases wherever the amount of potash driven over with these gases would justify the expense. Similarly, a desire to eliminate waste led the steel industry several years ago to begin the manufacture, from spent sulphuric acid, of ferrous sulphate, commonly known as copperas or green vitriol. The production of this salt for the year 1919 amounted to almost 60,000 net tons, practically all of which we can be reasonably sure was produced by the steel industry.

This salt is used in paper making; in the tanning of some leathers; in water and sewage purification; in the manufacture of fertilizer from packing-house waste; on the farm as a spray and disinfectant for the eradication of weeds and the prevention of certain diseases among plants and animals; and in the preparation of inks, certain pigments, shoe blacking, ferric sulphate, stock foods and a few drugs and medicines. A new use for this salt has been found in the briquetting of blast-furnace flue dust, in which process it acts as a cement, making the briquets produced by pressing hard and strong. It is also used in the purification of artificial gas from hydrogen sulphide and hydrocyanic acid gases, for which purpose there are two general methods, known as the dry and the wet methods. In the dry processes the sulphate is mixed with equal volumes of lime and moist sawdust, which are then pressed into a cake and roasted. The roasting burns out the sawdust and leaves a porous mass composed of iron sesquioxide and lime intimately mixed and ready to be charged into the gas scrubber. In the wet processes, which are more efficient in the removal of hydrocyanic acid, the gas is scrubbed with a concentrated solution of the sulphate, and ferrocyanides are obtained as byproducts. A lime and iron oxide mixture similar to that just described for the dry process is now obtained by one of our companies in the purification of mine waters. As this mixture does not require roasting, it is easier to prepare than the sulphate mixture and is very effective and economical as an agent for removing sulphur in coke-oven and other retort gases made from coal.

It should be noted in passing that a similar desire to utilize what would otherwise remain waste products urged us many years ago into the manufacture of cement from blast-furnace slag, of phosphate fertilizer from basic slag, and of paints containing zinc oxide and white lead or iron sesquioxide as base pigments. Although viewed with much prejudice and suspicion in the beginning, the high quality and economic importance of these byproducts of the steel industry are now generally recognized.

Supplying Ammonia and Coal-Tar Products

Again, the change from the beehive to the byproduct method of coking coal has brought the steel industry into the most intimate relationship with the chemical industries, particularly the coal-tar branch. This change has created an almost unlimited supply of ammonia and coal tar, the chief raw material used by the coal-tar chemists. Ammonia can now be produced at the byproduct plant in three forms—namely, as ammonium sulphate, as concentrated ammonia liquor and as ammonium chloride. The chief outlet for this ammonia lies in the direction of the fertilizer industry, for which purpose the sulphate is employed. The salt is seldom applied alone to the soil, but is used in the various fertilizer mixtures, for which purpose it is well adapted because it will neither revert the acid calcium phosphate nor react with the other fertilizer ingredients to render unavailable any part of its own nitrogen content. It is especially beneficial to some of our soils which contain an excess of the alkalis and to other that lack sulphur. In the latter it fulfills the double purpose of supplying both nitrogen and sulphur, two elements essential to plant growth. A process for recovering ammonia in the form of the chloride, which happens to be the form in which about 90 per cent of the fixed ammonia is given off by the coal, has been recently developed so as to be applied on a large scale. The perfecting of this process will make it possible to produce this salt in large quantities and possibly in a highly refined state. Thus another element has been added to the list of coke byproducts, and the field for the disposal of byproduct ammonia has been widened.

Omitting alcohol and the compounds of sulphur and hydrocyanic acid that can be made or recovered from coal gas, the other products of the byproduct plant are the chemical compounds benzene, toluene, xylene and naphthalene, and the mixtures known as light-runnings, wax, resin and tar. Commercially, the first three compounds, as well as mixtures of these substances, are known as benzol, toluol and light and heavy naphtha. These compounds, together with tar, form the raw materials for the coal-tar branch of our chemical industries. The finished products that can be made from these raw materials are numbered by hundreds, but, classified, the finished coal-tar products consist of dyes, color lakes,

explosives, disinfectants, medicines, phenolic resins, flavors, photographic chemicals and perfumes, in about the order of their total money values per annum. According to the statistics compiled by the Census Bureau, the weight of these products for 1919, excluding disinfectants and explosives, amounted to 82,532,400 lb., and they were valued at $84,515,500, or an average price per pound for all finished products of about $1.05. A comparison of this average price with the 1919 prices obtained for the crude products at the coke works, which ranged from ⅛c. per lb. for tar to 10c. for the purest naphthalene, shows how the values grow in passing through the hands of a chemist. In addition to these finished coal-tar products, there were produced in unknown quantities several crude and intermediate products, the total value of which is stated to be approximately $49,000,000.

The Rise of the Coal-Tar Industry

At this point it may be of interest to note the rapid growth of this branch of our chemical industries. In 1914 the total value of all the coal-tar chemical products produced in this country was approximately $9,000,000, and with the exception of tar refiners and about seven small plants engaged in assembling imported intermediates into dyes, there were no establishments devoted solely to the manufacture of finished coal-tar products of any kind. Now, according to the recent census taken by the United States Tariff Commission, the total number of firms engaged in the manufacture of coal-tar products in 1920 was 213, of which 82 were engaged in the manufacture of dyes alone. These firms produced more than 206,000,000 lb. of the semi-finished products known as intermediates and more than 67,000,000 lb. of finished dyestuffs. The discrepancy between the tonnage of intermediates and finished dyes is brought about in two ways—namely, some of the intermediates are produced from other intermediates, hence may appear twice in our total, while others may be used for the manufacture of other substances than dyes. All of these intermediates can be made from benzene, toluene, xylene and naphthalene, and are very numerous, as many as 46 being derived from naphthalene alone. Concerning the number of dyes, our chemists made 360 separate dyes in 1920, some of which were never made before. We hesitate to give any figure as representative of the number of other coal-tar chemicals, for new ones are being discovered with bewildering frequency. If we can do so without appearing unduly boastful, we would like to declare in this connection that American chemists during the past 5 years have led the world in the discovery of new coal-tar chemicals.

Another comparison of perhaps greater interest to us is this: The 82,500,000 lb. of finished coal-tar chemical products produced in this country during the year 1919 is equal to only a little more than one-third of the total weight of the benzene products and less than one-tenth of the tar produced by the Steel Corporation alone during the same period. Now, the processes of the coal-tar chemist are all synthetic, so that his finished products generally show a gain in weight over the basic raw materials, except in the case of tar, of which only about 15 per cent is available for synthetic purposes. So, keeping in mind that the Steel Corporation probably made considerably less than half of all the tar and primary benzene products produced in this country, we have evidence enough that the production of coal-tar chemicals was not limited by a scarcity of raw materials. Yet, for this reason or that, we have found the coal-tar chemists importing some of these same raw products.

Need for Better Relations Between the Two Industries

Let us cite one case to illustrate a point we wish to make. A certain byproduct coke plant operator, under the impression, which he had gained in dealing with the coal-tar chemists themselves, that for the manufacture of certain naphthalene dye intermediates the purest naphthalene obtainable was required, proceeded to install at great expense apparatus wherewith he would produce practically c.p. naphthalene, or at least naphthalene with melting and boiling point ranges of 1 deg. This gentleman then felt reasonably sure of getting a good portion of the business in high-grade naphthalene, but less than 2 months after completing his fine new plant he found his best customer importing naphthalene at 3c. less per pound than he was asking—yes, but of inferior grade and with a boiling point range five times as great. Now, either this dye maker had intentionally misrepresented his requirements with the idea of getting something for nothing, if he could, or he suddenly discovered he did not need as good a grade of naphthalene as he thought. This incident illustrates a lack of sympathy and co-operation between these two industries that we hope is, or will soon become, very rare.

Fortunately, and also unfortunately, the steel industry does not rely upon the coal-tar chemical industry in disposing of these coke byproducts and neither does the coal-tar chemical industry rely upon us for its supply of raw materials entirely. The steel industry finds a ready sale for all its benzene and toluene and a part of the naphtha as motor fuel, while the remainder of the naphtha and all of the naphthalene and tar can profitably be used as fuel in the steel mills. On the other hand, the coal-tar chemists can look to the gas manufacturers for many of their basic raw materials, and, indeed, so far as the refining of tar is concerned, they rather prefer certain gas tars to coke-oven tar, as the former usually contains a higher percentage of the more desirable light and middle oils. This is the unfortunate side of this condition, that it does not promote the spirit of sympathy and helpfulness that goes with a mutual dependence. All tar, however, contains a high proportion of pitch, for all of which it is difficult to find a ready market But the coal-tar refiner would be relieved of his "burden of pitch" and the byproduct coke operator would receive more money for his tar, if some plan were evolved wherein the tar could be roughly fractionated at the coke plant, where the pitch could be mixed with raw tar and used as fuel or charged into ovens and converted into coke.

Some Indirect Relationships

Leaving for a time the points of direct contact between these two industries, let us examine briefly their indirect relationships. For, whether the matters just discussed are viewed with concern, as being of importance, or with indifference, as becomes trifles of little consequence, the steel and chemical industries are indirectly connected in ways that are vital to the welfare of both. To prove this statement the mere mentioning of a few of these direct relationships is all that is needed.

One of these indirect relationships has to do with the

fact that certain products of these two industries are absolutely interdependent for their effectiveness. We consider, for example, the dependence of liquefied and compressed gases upon the high-tension seamless steel tank, and then reflect that without the development of and the demand for such gases there would be no demand for the tanks. In the latter case the steel industry would have missed a good business, for, taking the case of compressed oxygen alone, the 1,200,000,000 cu.ft. or more of this gas compressed yearly requires the constant use of about 2,000,000 tanks to contain and market it. Similarly, we find steel tubing and ammonia working together in our ice plants, drills and powder in our mines, firearms and explosives on our battlefields and on our hunting grounds, and automobiles and gasoline or benzene everywhere.

Again, we find that the steel and chemical industries are connected in a similar indirect but vital manner through their more direct relations to certain other industries. In a word, both steel and chemicals are first essentials to many industries. We have already pointed out the interdependence of our basic subsidiary industries, upon which all our other industries depend, and now we wish to call your attention to the fact that some of our most important special industries are so completely dependent upon steel and chemicals that if they were denied either of these two classes of materials, these industries would be totally ruined. A notable example is supplied by the electrical industries. Without chemicals for batteries and insulating materials, or without steel for magnets, armature cores, transformer cores and other vital parts of electrical machinery, the whole industry would be handicapped and certain branches would be impossible. Similar conditions with respect to steel and chemicals prevail in the telephone and telegraph industries, the textile industries, the rubber tire industry, and in many other industries of more or less importance.

Our National Safety and Our Industrial Progress Dependent Upon Steel and Chemicals

Before leaving our subject we would speak of one other phase of the indirect relations between these two industries. This matter, while it is less tangible than those things we have just been discussing, is nevertheless of vital importance. We refer to the common relation of the steel and chemical industries to the welfare and safety of our country. It is self-evident that the strongest nation is the independent nation—that is, the nation that does not have to rely upon its neighbors for any of the basic or critical supplies. Such an independence is based upon two commodity factors—namely, natural resources and the industries to develop them. As to the natural resources, this country has been blessed with a full line with the exception of combined nitrogen, which deficiency, fortunately, can now be supplied by our by-product coke ovens and our prospective nitrogen-fixation plants. Fortunate for us, also, we can now say, although not with pride, since we were forced to it, that the last link in the chain of our industrial independence has been forged. This link is about to be subjected to the severest commercial tests, and whether or not it can withstand the tension of selfishness, prejudice and ignorance at home and the strain of competition from abroad depends upon how big a load we permit these things to become.

This new link in our industrial chain you will recognize as the coal-tar branch of our chemical industries. Its present importance to us in peace times is indicated by the value of its products for 1919, which we have just stated. Its future importance we can only imagine, for it is still in the rough and capable of much further development. Indeed, none of our other industries presents such a field of unexplored potentialities. For its importance in war times, we need only to refer to its position in the late World War. If Germany ever again is the maker of our dyes, German poison gas will again suffocate our soldiers. To overcome prejudice and misrepresentation at home, let all our people know we can and do make as good dyes as were ever made prior to the war. Dyes, like the different varieties of steel, can be misused and also injured by the way in which they are applied. The excuse we so often hear that our colored textiles fade because they are dyed with American dyes is a fallacy that may cover either cupidity or ignorance in the proper use and application of our dyes. To overcome the mistakes of ignorance, which, by the way, are mainly of a commercial nature and not of the technology of coal-tar chemistry, requires time, experience and the closest co-operation of all those concerned. Since they compose the two groups that would be most seriously affected by the destruction of this industry, the last part of this statement should be especially emphasized among both the makers and the coal-tar chemists, who, we fear, are not always so frank and business-like in their dealings with us or with the public as they should be, for their own good.

While we maintain that all our industries are equally important to the physical comfort and general welfare of our people, we can also say that no others have contributed so much to our safety and progress as the steel and chemical industries. In times of war they have supplied our chief means of defense and in times of peace they have furnished us with tools wherewith we have hewn our way to material successes. And now we plead for more sympathy and co-operation in these industries to the end that each may continue to contribute more and more to the security and prosperity of our own nation and to the advancement of all mankind.

Pittsburgh, Pa.

Italian Olive Oil Industry

The Italian Government is considering a project for joining all the growers of olive trees into an association to do away with antiquated methods of cultivation, reports the special correspondent of CHEMICAL & METALLURGICAL ENGINEERING. The association is to be maintained by the payment of a fee varying according to the number of plants cultivated by each member.

The Italian exports of green olive oil during the first half of 1921 were 1,394 tons, against 798 tons in the corresponding period in 1920 and 416 tons in 1919. Of these, 621 tons went to the United States, 92 to France, 137 to England, 53 to Switzerland, 10 to Australia, 26 to Tripoli, 110 to Argentina, 38 to Brazil, 17 to Chile and 20 to Uruguay.

The Italian imports of green olive oil in the first 6 months of 1921 were only 4 tons. Imports of edible, or pure, olive oil were 2,441 tons, against 814 tons in the first 6 months of 1920 and 5,720 tons in the corresponding period of 1919. Of the edible product imported in the first half of 1921, 203 tons came from Greece, 328 from Spain, and 1,239 from Tunis, the remainder being divided among other countries.

Manufacture of Cellulose Nitrate for Pyroxylin Plastics

Preparation of Tissue Paper or Linters for Nitration—Methods of Nitration: The Pot Method and Its Modifications; Nitration in Centrifuges; the Displacement or Thomson Process—Purification of Cellulose Nitrate: Washing; Pulping; Bleaching; Drying by Various Processes

By J. R. DuPONT

As a general rule, pyroxylin plastics are prepared by mixing a certain grade of cellulose nitrate with camphor and denatured alcohol. Sometimes for the sake of economy the camphor and alcohol are replaced partly or entirely by substitutes which will produce a more or less perfect plastic. Pyroxylin plastics are usually marketed under a trade name such as celluloid, viscoloid, pyralin or fiberloid.

Of the many possible cellulose nitrates, all of which have the general formula $C_{24}H_{40-n}O_{20-n}(ONO_2)_n$, only those having a nitrogen content of from 10.5 to 11.4 per cent are used in the manufacture of pyroxylin plastics. These are generally known as nitrocellulose, pyroxylin or soluble cotton, and their manufacture is a highly specialized operation, since the properties of the finished plastic are largely dependent upon those of the pyroxylin used.

Types of Cellulose Used as Raw Material

Many kinds of cellulose have been recommended for the preparation of cellulose nitrate to be used in making pyroxylin plastics, but so far, in Europe and in America, only two are used: tissue paper and cotton linters. The tissue paper is made of specially prepared and bleached cotton rags, weighs from 20 to 25 g. per square meter and has a thickness varying from 0.0025 to 0.0035 in. It has to be of very uniform composition and color, free from specks, hard knots or sizing, and is delivered to the plastic manufacturer in rolls weighing from 200 to 300 lb.

For use in this industry, cotton linters are submitted to a special purification to remove dirt, hulls and grease, and they receive the best bleaching possible, keeping in mind that an excess of treatment will be prejudicial to the quality of the finished product. So far in this country tissue paper has been mostly employed, but in Europe cotton is quite often used, and by employing proper acid mixtures cotton gives as good cellulose nitrate as paper. From an economical point of view it seems probable that in the future linters will supplant paper in the manufacture of pyroxylin plastics, as the cost of the former is about one-third that of the paper. Of all other different kinds of cellulose tried (flax, wood pulp, etc.), none so far has been utilized because of too poor nitration obtained or too colored nitrates produced.

Drying of Cellulose

As received the tissue paper or cotton has a moisture content too high to permit direct nitration, consequently it has to be dried before being used. This drying operation is very important, as too much moisture in the cellulose (above 1 per cent) will cause the following troubles: Weakening of the acid bath; irregular nitration, which will give a poor solubility; low yield caused by the breaking up of the cellulose nitrate fibers as a result of the rise of temperature produced by the contact of water with the acids; production of muddy acid, which will be prejudicial to the making of a first-class transparent plastic; acceleration of the production of N_2O_4, which will affect both the yield and the stability of the cellulose nitrate.

Drying the tissue paper is ordinarily done after it has been cut into strips of various sizes, which are carried by air displacement into a closed room, where, by hot air circulation, the drying is effected. In the case of cotton, the drying is done by placing the carded linters in heated and ventilated chambers, where they stay a variable time according to the moisture content, the temperature of heating and the efficiency of the ventilation.

Linters may be dried more efficiently in continuous driers similar to those used in the textile industry, since these give a greater production and also more uniform drying.

Nitration Bath

The nitration bath is formed from a mixture of nitric and sulphuric acids in variable proportions, and each factory has adopted a special formula which gives the best results for a determined cellulose. In general the ratio of nitric to sulphuric is about 1 to 3. This corresponds to a percentage composition of: HNO_3, 19 to 20; H_2SO_4, 60 to 61; H_2O, 21 to 19.

Table I shows the results of laboratory research on different nitration baths. These data were obtained on paper using 50 g. for each nitration, with a ratio of acids to paper of 100 to 1. As would be expected, in practice the yield obtained after washing and bleaching is considerably lower and is around 145 to 148 per cent.

TABLE I. LABORATORY RESULTS WITH VARIOUS NITRATION BATHS

	Mixed Acid						Cellulose Nitrate		Solubility in:	
No.	HNO_3, Per Cent	H_2SO_4, Per Cent	N_2O_4, Per Cent	H_2O, Per Cent	Temp., Deg. C	Time, Min.	Yield, Per Cent	N_2, Per Cent	5 Per Cent Camphor	Acetone

Time of Nitration

The nitration time is variable according to the composition of the mixed acid, the kind of cellulose used

Publication and translation rights reserved by the author.

and the temperature of the acid. In case of tissue paper the speed of reaction is in direct proportion to the thickness and also to the temperature at which the nitration is conducted. For economical results the time of nitration is rarely over 60 minutes—that is, the total duration, including the filling of the pots with acid, the dipping of the paper and the whizzing of the cellulose nitrate. This leaves the real time of nitration varying from 25 to 35 minutes, which is enough if the composition of the mixed acid is correct.

For linters a longer time of nitration is generally employed, but by increasing the temperature of the acid, which will speed up the reaction, practically the same time can be used.

Temperature of the Mixed Acid

The temperature of the acid varies according to the cellulose used, and each manufacturer has adopted a temperature which gives him the best results. When working with tissue paper the acid temperature is kept around 30 deg. C.; with linters near 35 deg. C. The higher the temperature of the acids the quicker will be the reaction but also the greater the chance of breaking up the fibers of the cellulose nitrate formed, which will lower the yield.

Combined with too much moisture in the cellulose, excess of heat will produce partial decomposition of the cellulose nitrate. Not only is this practice, often observed, a costly one, but also the acid is soon contaminated with N_2O_4 which, in amounts above 1 per cent, will affect the yield and lower the stability of the cellulose nitrate produced. The most trouble arises during the period of warm and damp days when it is difficult to keep down the acid temperature and artificial cooling has to be employed.

Quantity of Acid Used

The type of cellulose and the method of nitration have a direct influence upon the amount of mixed acid required for nitration. With tissue paper the ratio of acid to paper is generally 100 to 1, but if the paper is stirred during nitration the proportion can be reduced to 85 to 1. In the case of linters the ratio is usually between 50 to 1 and 60 to 1.

Typical Plant Data

Table II gives data which are typical for the commercial production of cellulose nitrate from tissue paper and linters.

Nitration Methods

Three general methods of nitration are employed in pyroxlin plants: Pot method, centrifuge method and displacement process.

Pot Method

Hand Dipping With Individual Pots.—In this first method, which was much used in the early days of celluloid manufacture, the dry cellulose was dumped in stoneware pots containing the mixed acid; after nitration, which required from 45 minutes to 2 hours, the cellulose nitrate was separated from the spent acid by different means, but all based on exerting pressure on the cellulose nitrate. After most of the acid was thus expelled, the nitrate was drenched in water. As the loss of spent acid was very great and owing to the difficulty of washing the compressed cellulose nitrate, the next step was the introduction of the centrifuge as a means of separating the spent acids from the finished product, a method which is practically the only one used today.

The capacity of the pots used at first was only 8 to 10 gal.; as the production was small, the capacity was later increased to 100 gal. The small pots were ordinarily carried by hand to the acid-extracting machine, but as the larger ones were too heavy, they were made stationary, supported by two iron posts. By a cock the acid was drained off after nitration and the cellulose nitrate forked into the whizzer. The abundant fumes obtained during the process were collected by a hood and carried outside by a fan.

Table Method.—In order to get a greater production and reduce to a minimum the size of the nitration room, the pots were placed on a turntable, and this table method (which was first designed by Hyatt) is still used with but very little modification.

The apparatus is composed of a circular turntable upon which six or eight iron pots of special shape are supported by iron arms. Outside the table is a whizzer so placed as to reduce to a minimum the splashing of the acid when the pots are dumped. Above the pots and the whizzer is a large hood where the fumes are collected and sent outside by a suction fan. The apparatus is operated as follows: The first pot is filled with mixed acid at the proper temperature and the dry cellulose is placed by hand in the acids and dipped with aluminum forks or by a specially constructed stirrer; this done, the table is turned by hand so that the second pot is placed in front of the acid feed pipe. The second pot is then filled with acid, the dry cellulose immersed and the operation repeated. The number of pots on the table is determined by the duration of the nitration, so that when the last pot is ready to be filled with mixed acid the nitration of the first is completed and it can be dumped in the whizzer. With an average of 45 minutes for the total time of nitration, using eight pots, a complete turn of the table takes place every 45 minutes, each operation taking the following time: Filling the pot with acid, 3 minutes; dipping of the cellulose, 4 minutes; duration of nitration, 31 minutes; dumping and whizzing of the cellulose nitrate, 5 minutes.

As the pots have a capacity varying from 15 to 30 lb. of cellulose, the production per hour varies from 232 to 464 lb. of cellulose nitrate, admitting an average yield of 145 per cent. As to labor, six men are required to take care of the table. This method of nitration, used in the United States principally for the nitration of tissue paper, has the following disadvan-

TABLE II. TYPICAL PLANT DATA

H_2O	19.78	20.69

tages: Irregular solubility of the cellulose nitrate due to the fact that the cellulose is generally dipped by hand with no stirring during the nitration; great loss of nitric acid fumes, as the pots are not covered. In addition, the fumes are very troublesome for the men and keep the cost of repairs very high. For these reasons the table system of nitration is generally replaced by the use of special nitration units as used in the manufacture of cellulose nitrate for the making of explosives.

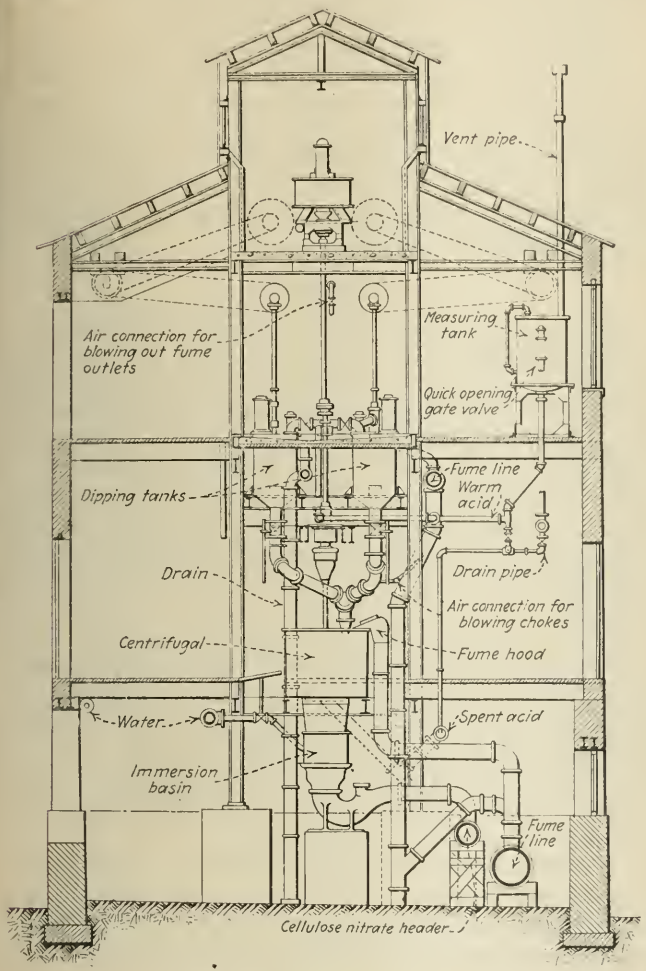

FIG. 1. CELLULOSE NITRATE PLANT USING MECHANICAL DIPPING TANKS

Mechanical Dipping Tanks.—This special machinery is composed of four separate dipping tanks and one centrifuge, forming one unit. Each tank (which is made of special acid-resisting iron) is cylindrical and provided with two stirrers which not only stir the cellulose during the nitration but effect the dipping of the cellulose when placed in the acids. Situated at the bottom of each dipping tank is a pipe of large diameter closed by a valve, connecting the tank with the centrifuge which is situated on a floor below. Fig. 1 gives a general idea of the arrangement of a plant of this type. A series of dipping tanks is shown in Fig. 2.

The nitration operation is carried on as follows: The tank is first filled with mixed acid of the correct temperature. The cotton or shredded paper is then dumped in the acid, being quickly immersed by the rotating stirrers. The nitration is permitted to go on, generally 30 minutes, and when completed the bottom valve of the tank is opened and the acid and cellulose nitrate fall directly into the centrifuge, where the acid is whizzed out, going by gravity to the spent acid tank. The centrifuge has a bottom discharge which permits the direct dumping of the cellulose nitrate into the first washing tank. The capacity of the dipping tanks is ordinarily about 1,600 lb. of mixed acid and the total duration of the nitration is generally 45 minutes. Using a ratio of 1 lb. of linters to 50 lb. of acid, the total production of a unit per 10 hours would be 2,560 lb. of cellulose nitrate, admitting a yield of 150 per cent. The centrifuge shown in Fig. 3 has a diameter of 42 in. and is directly driven by a 40-hp., 440-volt electric motor turning at 1,170 r.p.m. This system of nitration has many advantages over the other methods—it reduces the labor required, minimizes the production of fumes and gives a very uniform nitration—so that in the future it will be entirely used.

Centrifuge Method

In this method, used mostly abroad, the nitration is made directly in a centrifuge with a basket specially constructed to keep the mixed acid away from the bearing of the machine. The basket can be rotated at two different speeds and can be emptied of the spent acids by a cock placed on the side of the casing. The principle of this method of nitration is based on the fact that if the basket of the centrifuge is made to rotate at a low speed (30 r.p.m.), the acid will be kept constantly in motion and will thus give a better nitration.

When the nitration is completed—that is, after 25 to 35 minutes—the acid-draining valve is opened and the high speed (1,000 r.p.m.) is put on, so as to remove as much as possible of the spent acid. This centrifuge, in which the temperature of the acid can be controlled (as the casing of the basket is jacketed), has a maximum production of 300 to 450 lb. of cellulose nitrate per 10 hours, admitting an average yield of 150 per cent, varying with the capacity of the basket. This method of nitration, which presents certain ad-

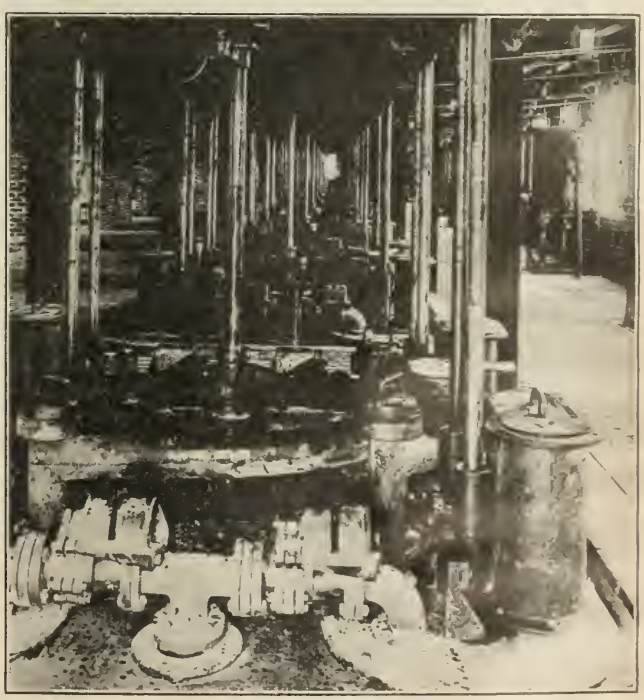

FIG. 2. MECHANICAL DIPPING TANKS FOR NITRATION

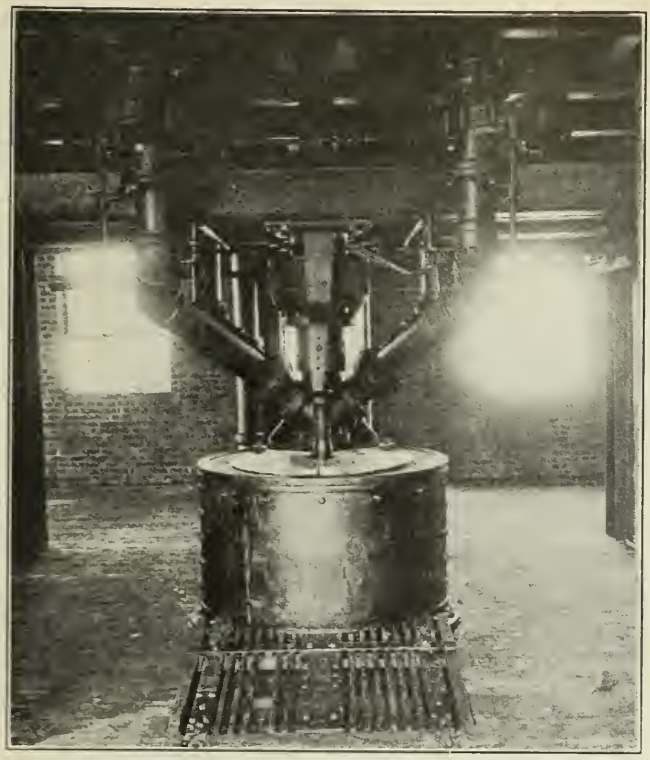

FIG. 3. CENTRIFUGE FOR CELLULOSE NITRATE

vantages, has not met with much success, on account of the cost of the installation, which is great when large quantities of cellulose nitrate are required.

Displacement Process

The displacement or Thomson process is based on the fact that if water is carefully run on the top of mixed acid in which cotton is nitrated and the acid drained out slowly, the water will displace the acid from the cellulose nitrate, not causing mixing of water and acid, which would liberate heat and thus cause decomposition of the cellulose nitrate.

The apparatus used is composed of four low cylindrical earthenware vessels, forming one unit; the conical bottom of each vessel supports a removable perforated bottom plate and terminates at the lower end in a cock for draining the acid. Fitting the top of the cylinder is a perforated plate, and on the side of the apparatus are two pipes supplying the acids and the water. A hood carried on a rail collects the fumes during the dipping of the linters, the fumes being sent outside by a fan. The process of nitration is as follows:

The hood is placed above the vessel which is filled with the mixed acid (700 to 800 lb.) and from 20 to 22 lb. of dry linters is dipped in the acids. This operation completed, the perforated top plate is placed above the linters so as to keep them immersed in the acid; then about 1 in. of water is slowly run on the top of the plate so as to prevent the formation of fumes. The hood is carried off and the nitration is then permitted to proceed from ½ to 1 hour. The nitration competed, the bottom drain cock is opened and at the same time water is permitted to run on the top of the plate. Great care should be taken so that the speed of the acid and the water is the same; the maximum speed for the withdrawal of the acid is around 17 lb. per minute.

The acids up to a density of 1.65 are kept in a special tank and considered as true spent acids which will be fortified with strong mixed acids to be used again in subsequent nitrations. The weaker acids are sent back to the acid manufacturer, keeping in mind that acids that are too weak will attack the iron containers. The total duration of the operation is 2½ hours, this corresponding to a production of about 500 lb. of cellulose nitrate per unit in a 10-hour shift.

This process has many advantages, which stated briefly are: Reducing to a minimum the production of troublesome fumes; lowering the amount of acid consumed; eliminating the use of a centrifuge; reducing the time of washing and consequently the quantity of water used, etc. However, few celluloid factories have adopted this process, as it is practical only when linters are used.

Washing

As soon as the nitration is completed, the cellulose nitrate is dumped into a tank containing a large quantity of water, where the mass is vigorously agitated by hand or mechanically, so as to reduce to a minimum the heating which will result from the contact of water with the acid. From this first washing tank the cellulose nitrate is sent ordinarily by gravity to the washing tank proper, situated on the floor below. If the prewashing is not properly made, decomposition of the cellulose nitrate will take place, a fact too often observed.

The real washing of the cellulose nitrate made with tissue paper is done in wooden tanks of rectangular or elliptical shape, which are generally covered with perforated aluminum sheets and in which a hollow drum supporting aluminum paddles is rotated, assuring the constant motion of the cellulose nitrate in the water. By changing the water frequently, the cellulose nitrate is washed until nearly neutral.

The time of washing varies with the retention of acid by the cellulose nitrate, but from seven to ten changes of water are required, the machine being kept in motion for 30 minutes between changes.

Pulping

After the cellulose nitrate has been washed, it is pulped in beating machines in the same manner that cellulose is converted into paper pulp. However, the

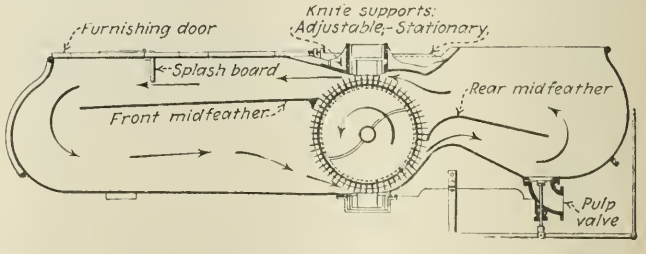

FIG. 4. DUPLEX BEATER FOR PULPING CELLULOSE NITRATE

ordinary type of beater is generally replaced by the Duplex beater, which, as will be seen from Fig. 4, has two sets of stationary knives, thereby doubling the production of the machine.

Although pulping permits better bleaching and the production of a more stable cellulose nitrate, it is not always practiced in factories using tissue paper, as the loss during the operation is great if the installation is not right. Nevertheless it would seem that this

operation is indispensable for the production of a first-class cellulose nitrate and that the loss of flock might be minimized by installing save-alls of the right kind.

Bleaching

The bleaching of the cellulose nitrate is very important for the production of transparent and ivory plastics, and each factory has adopted formulas which vary with the grade of cellulose employed. The two methods generally employed use potassium permanganate and chlorine, respectively.

When employing potassium permanganate, a solution of 2 per cent of the weight of the cellulose nitrate is used and the water is made slightly acid with sulphuric acid. As soon as the reduction of the potassium permanganate is complete, which takes from 1 to 2 hours, the cellulose nitrate is washed and the brown color is removed by oxalic acid or, better, SO_2.

In the second method, chlorine is employed, using solutions of bleaching powder or liquefied chlorine generally of 1 per cent strength. The time of bleaching varies from ½ to 1 hour. Great precautions have to be taken to remove all trace of chlorine, and sometimes sodium thiosulphate or, better, sodium sulphite is used as an anti-chlor, since chlorine present in the cellulose nitrate will rapidly cause decomposition.

After bleaching, the cellulose nitrate is given from seven to ten washings with hot water and, during the first three, a solution of sodium carbonate is added so as to neutralize exactly the acidity of the cellulose nitrate. Great care must be taken to remove all traces of alkali, which, if left in the cellulose nitrate, will have a tendency to provoke discoloration of the finished celluloid. At this stage the nitrated cellulose is ready to be dried, and before this operation the finished product is whizzed so as to reduce the water content to about 35 per cent.

Purification of Cellulose Nitrate From Linters

The purification process as given above is what is generally followed for cellulose nitrate made with tissue paper, but when linters are used, the treatment has to be made very carefully so as to obtain a stable finished cellulose nitrate. Generally the prewashing is followed by boiling the cellulose nitrate in circular boiling tubs with slightly acidified water, the operation lasting generally 4 hours. After boiling, the cellulose nitrate is pulped and sent to the poaching tanks (Fig. 5), where the bleaching and finishing of the purification are accomplished.

For the washing and purification only filtered and treated water can be used, and many factories have trouble in obtaining or keeping the water up to standard.

Drying the Cellulose Nitrate

The drying of the cellulose nitrate can be done by the following methods: 1. By pressing. 2. By pressing and heating. 3. By centrifuging with alcohol. 4. By alcohol displacement. 5. By alcohol and pressure.

Drying by Pressing.—The pulped cellulose nitrate after whizzing is first pressed in slabs 20 x 20 in. and of average thickness of ¾ in., between heavy cotton sheets in which the slabs are wrapped. The special hydraulic press used develops a pressure of 3,000 to 3,500 lb. per sq.in., and when enough slabs are made they are piled and placed in another hydraulic press working with the same pressure. When most of the water is thus extracted, the pressure is cut off and the wet wrappers are replaced by dry ones and the slabs again submitted to pressure; after repeated pressing, generally twelve to fifteen times, the cellulose nitrate is considered dry—that is, it has a water content varying from 1 to 1½ per cent. This method, in which only the cotton wrappers are dried by heat, is used mostly in Europe, where labor is cheaper.

Drying by Pressing and Heating.—In this process the wet cellulose nitrate is first mixed with camphor and generally run through a rotary cutter to obtain a perfect mixture, and slabs are made as previously explained. The slabs are pressed so as to reduce their water content, then are taken out of the wrappers and transported to drying rooms, where the temperature is continuously kept at 37 deg. C. by means of hot air circulation. From 18 to 24 hours is required to dry the cellulose nitrate. This method, employed here and abroad, gives a finished product with a variable moisture content, is wasteful of camphor, and tends to develop acidity due to the prolonged heating.

Drying by Centrifuging With Alcohol. — This process of drying, mostly used in Europe, requires the use of a special centrifuge in which the basket has two perforated walls leaving an annular space in which the pulped cellulose nitrate is packed. The machine can be made to run at low or high speed and the alcohol is admitted by a perforated pipe placed in the center

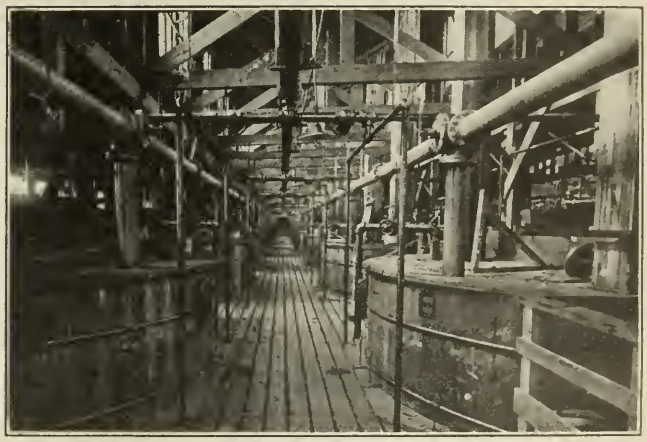

FIG. 5. POACHERS FOR CELLULOSE NITRATE FROM LINTERS

and held in place by the cover of the centrifuge, which can be made air tight. After the moist pulped cellulose nitrate has been packed in the basket and the cover put in place, the high speed is shifted on so as to remove most of the water; this done, the machine is made to run at the low speed, and a known quantity of weak alcohol from a preceding operation is sent through the feed pipe; this alcohol displaces the water. This partial drying is followed by the use of 90 per cent denatured alcohol, which completes the drying process. Finally the high speed is put on so as to reduce the alcohol content of the cellulose nitrate as much as possible. The total operation takes about 1 hour, including the filling and the emptying of the machine, or a daily production of about 2,000 lb. of cellulose nitrate with an alcohol content of about 35 per cent. The alcohol required to obtain thorough drying is around 3 lb. per pound of cellulose nitrate.

Drying by Alcohol Displacement.—In this method of drying the moist pulped cellulose nitrate is placed in cylindrical tanks having conical bottoms, supporting

a perforated plate. The tanks, generally six in number, are placed in a circle, in the center of which is the centrifuge. A tank containing 90 per cent denatured alcohol is placed overhead and other tanks situated on a floor below collect the diluted alcohols which are forced on the cellulose nitrate by compressed air. This process works as follows: The cylindrical tanks are filled with the wet cellulose nitrate and in the first 90 per cent denatured alcohol is admitted. When the cellulose nitrate is completely covered with alcohol, the valve situated at the bottom of the tank is opened and the alcohol drained and collected and sent to the second tank. The first tank is then filled again with strong alcohol, and the alcohol drained from the second tank is sent to the third tank, from which it is sent to the tank containing the weak alcohol to be distilled. The alcohol collected from the second run in tank 2 is then sent to tank 3 and strong alcohol sent to tank 1. At this stage we have the first tank containing strong alcohol and cellulose nitrate free from water. The second tank contains medium strength alcohol and needs one more treatment with strong alcohol. The third tank contains only weak alcohol and will require two more treatments with medium and 90 per cent alcohol to be dried. As soon as the cellulose nitrate is dried—that is, after three treatments—it is dumped into the centrifuge so as to remove as much as possible of the alcohol. This method, in which loss of alcohol by evaporation is to be expected, requires about 2 lb. of 90 per cent alcohol to 1 lb. of pyro.

Drying by Alcohol and Pressing.—This is the dehydration process used by smokeless powder manufacturers. The wet cellulose nitrate is placed in a specially constructed hydraulic press having two pistons moving in opposite directions, the bottom one supporting a heavy perforated plate. The pistons fit exactly the cylinder of the press and a pipe placed at the top of the cylinder brings the alcohol. The bottom of the cylinder is first closed with the bottom ram and the wet pulped cellulose nitrate is placed in the cylinder and covered with a bronze plate. By means of the top piston a pressure of 3,000 lb. per sq.in. is exerted on the cellulose nitrate, forcing the water to run out through the bottom perforated plate. The top piston is then raised and denatured alcohol at 90 per cent is admitted on the top of the cellulose nitrate and sent through the cake under a pressure of 250 lb., which is then followed by a pressure of 3,000 lb. so as to expel most of the alcohol from the cellulose nitrate. The alcohol content of the dehydrated cellulose nitrate varies from 25 to 28 per cent, the strength varying from 87 to 89 per cent. The quantity of alcohol necessary for the dehydration varies from ¾ to 1 lb. per pound of cellulose nitrate treated. The diluted alcohol is collected in tanks and submitted to distillation. About 1 per cent of the cellulose nitrate is dissolved in the alcohol during the dehydration, but the loss consists chiefly of lower cellulose nitrates, the removal of which gives a cellulose nitrate of better stability.

When the cellulose nitrate is dried, it is ready to be mixed with camphor and alcohol and transformed in pyroxylin plastics.

For the illustrations accompanying this article, the author is indebted to the Charleston Industrial Corporation and the Downington Manufacturing Co.

A subsequent paper will deal with the manufacture of pyroxylin plastics.

Annual Report, Bureau of Mines

A brief summary of some of the investigations conducted by the Bureau of Mines during 1921 is given in the following paragraphs, which are based upon the annual report of the director.

An investigation of losses of crude oil through evaporation in storage and in transportation, conducted during the year by the bureau, disclosed losses of startling magnitude. It was found that in the few days in which crude oil is stored on the lease before being taken by the pipeline, the aggregate loss per year from evaporation amounts to about 122,000,000 gal. of gasoline in the mid-continent field alone. This has a value, at 22c. per gal., of $26,840,000, and represents about 3 per cent of the total gasoline produced in the United States from all fields and all sources. A large percentage of this loss could be prevented by the use of efficient equipment.

The bureau has pointed out the considerable losses which have resulted from the failure of many refineries to recover gasoline from uncondensed still vapors. The significance of this investigation is shown by the fact that one refinery in the mid-continent field is now recovering from still vapors approximately 400 bbl. of gasoline daily which before the installation of this equipment was either lost or burned as fuel under the boilers and stills. The value of fractionating towers at petroleum refineries, by means of which some companies have increased the yield of gasoline from crude oil by as much as 5 per cent, or 16⅔ per cent of the total gasoline yield, has been demonstrated. A special process, devised at the San Francisco station of the bureau, for cracking heavy oils and tars promises the recovery of large yields of gasoline and other lighter products, hitherto regarded as unrecoverable.

Production of Helium

The experimental helium plant at Petrolia, Tex., conducted under the authority of the Army and Navy Helium Board, was in operation during the year at various times, and helium was produced for short periods. A study of the practicability of storing this rare and non-flammable gas in mine workings was made at the bureau's experimental coal mine at Bruceton, Pa. At the cryogenic laboratory in Washington, D. C., liquid air in quantity is now being produced. The primary object of this laboratory is to investigate gases and liquids at low temperatures, with special reference to the separation of helium from natural gas.

Molybdenum and Zinc

The bureau investigated the properties and possibilities of molybdenum, of which the United States possesses the largest known deposits.

The cost of production of zinc, with the standard retort process, is now so high that it endangers the position of zinc as a cheap metal. Plans have been formulated for an investigation of proposed methods for the electrothermic metallurgy of zinc, with a view to increasing the recovery of metal and lowering production costs.

Methods for preparing caustic magnesia were investigated which determined that high-grade magnesia can be made from some varieties of magnesite hitherto believed to be unsuitable for this purpose. The bureau investigated dolomite as a substitute for the more costly magnesite in preparing refractories, and demonstrated that there can be obtained from Ohio dolomite a product superior in magnesia content to Canadian magnesite.

Deoxidation and Desulphurization in the Heroult Furnace

Three Methods of Working Up a Heat of Steel Are Described in Detail—Composition and Characteristics of Slags Are Noted, and the Opinion Is Expressed That Good Steel From Poor Scrap Is Merely a Question of Knowledge and Skill

By F. T. SISCO
Metallurgist

FOUR characteristics and advantages of electric steel are, in the order of their importance from the standpoint of an electric steel salesman:

(1) It is made to close chemical specifications.

(2) Free from excessive segregation.

(3) Free from more than traces of sulphur and phosphorus.

(4) A thoroughly sound and deoxidized product may be made.

Furnace practice as developed in the past few years has made the first advantage a certainty. Practically all electric steel is now being made in any desired analysis and to any tolerance in the specifications. The second item—freedom from excessive segregation—is a matter of mold design, use of proper sink-heads, correct pouring temperature and sufficient cropping. This question will not be discussed here.

By most manufacturers the third characteristic is met to a surprising degree, much of the electric steel now being turned out containing less than 0.02 per cent of both these elements. In fact, it is altogether probable that too much attention is being paid to the reduction of the phosphorus and sulphur, particularly the latter, sacrificing complete deoxidation and thorough soundness.

After close observation of Heroult furnace practice in four plants and covering a period of 8 years, the author has concluded that much is yet to be desired as far as quality in electric steel is concerned. Electric steel from the Heroult furnace may and does surpass the best basic open-hearth and even the best acid open-hearth steel in quality, but with few exceptions is still decidedly inferior to crucible steel. This inferiority is partly caused by insufficient knowledge of the proper conditions for deoxidizing the metal, and partly to the wrong assumption on the part of the electric furnace melter that the function of his final slag is primarily to desulphurize. As a result, he makes his slag with that in mind, removes all of the sulphur possible and depends upon ferromanganese, ferrosilicon and occasionally aluminum, added in the last 15 or 20 minutes, to accomplish his deoxidation. This dependence upon a ferro-alloy to deoxidize a bath of molten electric steel is putting the process in a class where it approaches open-hearth practice and is bound to produce a product that in some cases is little better than good open-hearth steel.

The great advantage of the electric furnace is the flexibility and accuracy of control of the heat, permitting any slag or an oxidizing, a reducing or even a neutral atmosphere. Not to take advantage of the reducing conditions possible to form a slag so reducing in character that deoxidation will be nearly complete without the aid of a ferro-alloy is to neglect one of the most salient features of the electric furnace.

The superiority of crucible steel is due to the perfect deoxidizing conditions obtained by melting muck bar or any first-class scrap in an atmosphere entirely free from oxygen, the melted charge being permitted to lie quietly until solid and gaseous inclusions present in the base used have time to rise to the top. This cleaning action is aided to a slight extent by the presence of one or more ferro-alloys melted with the scrap, which have in themselves a strong affinity for oxygen. To make a product equal to crucible steel, the electric furnace must duplicate these melting conditions as nearly as possible. Not only that, but the electric furnace, to be a commercial success, must produce a product equal to crucible steel from a cheaper base.

The metal ready for the deoxidizing slag (or white slag as it is commonly called), whether melted under oxidizing conditions in the electric furnace itself, as is the case with units of 8 tons or less, or delivered molten from an open hearth, as in the larger furnaces, is generally low in carbon, almost free from silicon, phosphorus and manganese and nearly saturated with both oxides and gases. It is the function of the white slag to aid in the complete removal of these oxides and gases, whether present in large or small amounts. Incidentally the slag also removes the sulphur more or less completely.

The amount of oxides and gases present in the molten bath depends wholly upon the melting practice; three general classes are: (1) Melting without oxidation. (2) Melting with partial oxidation. (3) Melting with complete oxidation.

Melting Without Oxidation.—This practice is confined almost wholly to melting for high-grade tool steels and ball-bearing steels where the base material is very pure. For making high-grade carbon tool steels a base of muck bar and washed metal is melted down either alone or combined with a varying amount of rolling mill crop ends in which the sulphur and phosphorus are both under 0.02 per cent. In charging the raw material, a small amount of limestone is placed on the bottom of the furnace and building the white slag commences as soon as there is a pool of molten metal around the electrodes. With this practice oxidation may be almost wholly prevented, the only function of the white slag being to aid in the removal of such oxides as are present in the raw material charged. This practice results in a steel which may easily be made the equal of the best carbon tool steel made by the crucible process and is duplicated on alloy steels by using a charge made up wholly of butts, crop ends and discards from their own mills. Needless to say, this practice produces the best electric steel, but is not able to compete in price with steel made from a cheap scrap or molten open-hearth metal.

The important feature of melting under a white slag is the use of a charge that is within the specified

limits in phosphorus, as none is removed in melting, and of material as free as possible from rust and scale.

Melting With Partial Oxidation.—This method is undoubtedly the best where a cheaper base is used and where fairly high-carbon steel is made. The practice consists essentially of charging limestone on the bottom of the furnace and then loading in the scrap. This consists of ordinary low-phosphorus material (0.04 per cent) such as crop ends, boiler plate and (if alloy steel is to be made) nickel or chromium-nickel scrap from automobile plants or rolling mills, or forging billet and bar crops. A clean scrap free from rust and scale is used and the charge regulated as much as possible so the carbon when melted will be 0.10 to 0.30 per cent below the requirement. The charge is melted cold and the slag which has formed is removed as soon as the charge is all melted. The resulting bath contains most of the oxidizable elements except silicon and phosphorus, which latter has been reduced by the very basic slag from about 0.04 per cent to below 0.02 per cent. Since the molten charge contains most of the carbon and manganese, the absence of more than small amounts of oxides is assured. The remainder is then eliminated by aid of the white slag which is immediately built up as soon as the first slag is removed. Table I gives a furnace log of a heat melted in this manner.

Melting With Complete Oxidation

This practice, the most common, has the advantage that the scrap is freed except for traces of all oxidizable elements—carbon, silicon, phosphorus and manganese. A portion of the sulphur is likewise eliminated down to the point shown in Table II. Complete oxidation is necessary when a low-carbon product is desired, and this process permits of the use of a very cheap grade of scrap, phosphorus as high as 0.08 to 0.10 per cent being reduced with ease to below 0.02 per cent. To facilitate the active oxidation which takes place, limestone is charged on the bottom of the furnace. Iron ore or roll scale, to furnish the oxygen, follows. If much fine scrap

uch as clippings or punchings are used, or if the scrap s rusted, the amount of ore or scale may be reduced. n the case of very rusty scrap, no ore is necessary. The charge is melted at a high temperature, oxidation being nearly always complete by the time the metal is melted. When very high-phosphorus scrap is used, more ore is often added as soon as the bath is nearly melted. This oxidizing slag, corresponding in analysis to the first slag in Table II, is removed entirely. If medium- or high-carbon steel is to be made, carbon in the form of crushed coke or electrodes is added to the bare metal to bring the carbon up to within 0.10 to 0.20 per cent of the required analysis. If the bath should then boil violently, a few shovelsful of crushed ferrosilicon would be added to kill the wild metal. White slag is now added in order to deoxidize and produce a sound steel. A deoxidizing slag must do the greatest amount of work in this melting practice, since oxidation is carried to a maximum. Great skill is required in this deoxidizing practice to produce a sound steel.

This class of practice includes duplexing. Metal as received by the electric furnace from the open hearth is in a very similar condition as to chemical analysis and amount of oxides present as ordinary scrap melted in the electric furnace with complete oxidation. In duplexing open-hearth metal for the production of high-grade ordnance and armor plate, the present practice is to deoxidize partly by adding 12 per cent ferrosilicon to the open-hearth metal just before tapping. This is good practice and decreases the amount of work thrown upon the electric furnace.

In every case, whether the melted steel is not oxidized at all, partly oxidized, or wholly oxidized, the function of the deoxidizing or white slag remains the same—to aid in removing oxides and gases, to reduce those oxides which rise to the surface of the bath and to eliminate sulphur.

White Lime Slags

There are two methods of building white slags. The first makes a white lime slag, pure white in color, which disintegrates rapidly in air to a fine white powder. It contains lime, coke and spar in the ratio of about 10 to 1 to 1 and contains about 70 to 75 per cent bases and 15 to 25 per cent acids (see Table III). As a slag it is not strongly reducing, but serves more as a covering for the metal while the bath slowly frees itself from its occluded oxides and gases. In building this slag lime is thrown onto the bare metal until it is covered. On top of this blanket of lime is scattered powdered coke. It is certain that some calcium carbide forms around the arc, which is immediately broken up by the atmospheric oxygen in the furnace as it spreads out from the electrodes, the carbon burning to carbon monoxide, CO. Fluorspar is added until the slag has the proper consistency. Some melters use silica sand and even powdered glass instead of fluorspar. Fluorspar, however, is a much better thinning agent than silica sand and has the advantage that it is a more active desulphurizer. In addition, it is undesirable to reduce the proportion of bases any more than is necessary to secure fluidity.

Deoxidation with this white lime slag is primarily a mechanical process, the small amounts of oxides and silicates in the bath slowly rising until seized by the slag and held partly in chemical combination and partly in suspension. Deoxidation, too, is never very complete with this slag. Even after the bath has been under the slag for 3 or 4 hours, metal tests show considerable wildness. When the heat is ready to tap, deoxidation is accomplished by adding ferrosilicon with a thorough rabbling as soon as the alloy is melted. When silicon specifications are low, it is almost always necessary to rabble in aluminum to put the bath in such condition that the metal will lie quietly in the molds after pouring.

There is only one advantage in using this slag: There is no appreciable carbon absorbed from the slag. The only possible justification for the use of a white lime slag is when very low-carbon steel is desired; even then the practice should be modified somewhat by having some carbide present. The disadvantages are many:

Deoxidation is too slow and too uncertain, making it necessary to add ferrosilicon or aluminum or both. While ferrosilicon or aluminum is very efficient and deoxidizes a bath completely in a few minutes, it is practically impossible for the heat to free itself from the non-metallic reaction products formed by the reaction between entrapped oxides and gases and the ferrosilicon or aluminum in the short time between the addition and tapping, causing "slag spots," which, even though they may be microscopic in size, are nevertheless sources of weakness. There is also no certainty that harmful oxides will be rendered harmless by silicon. Too often, in practice, a final heat test lies quietly, while the ingots poured are so "blowy" that they have to be scrapped. White lime slag and the more common white slag containing very small amounts of calcium carbide have no redeeming features with the exception of the fact that no carbon is picked up by the metal. The practice of using these slags in conjunction with subsequent additions of deoxidizers in the form of ferroalloys cannot be too strongly condemned; a steel is produced which may be passable in some instances, but usually it will not be of a grade that brings repeat orders from the buyer.

TABLE III. TYPES OF ELECTRICAL FURNACE SLAGS

	White Lime Slag—Not Reducing	White Carbide Slag—Very Reducing
SiO_2	17.57	7.48
FeO	1.33	0.35
Al_2O_3	3.12	2.17
MnO	0.36	0.05
CaO	62.45	65.82
MgO	11.65	13.78
CaS	0.87	2.26
CaC_2	None	4.54

Desulphurization with a white lime slag proceeds according to the reaction

$$CaO + \left\{\begin{matrix}MnS\\FeS\end{matrix}\right\} + C = CaS + CO + \left\{\begin{matrix}Mn\\Fe\end{matrix}\right\} \quad (1)$$

the carbon being present in small amounts from coke added to the slag and from the electrodes. It is probable that reaction (1) is aided by reaction (2) when calcium carbide is not present in considerable amounts:

$$2CaO + 2\left\{\begin{matrix}MnS\\FeS\end{matrix}\right\} + Si = 2CaS + SiO_2 + 2\left\{\begin{matrix}Mn\\Fe\end{matrix}\right\} \quad (2)$$

through small amounts of metallic silicon either added intentionally or reduced from silica (SiO_2) by the arc. It is also aided by reaction (3):

$$2CaF_2 + 2\left\{\begin{matrix}MnS\\FeS\end{matrix}\right\} + Si = 2CaS + SiF_4 + 2\left\{\begin{matrix}Mn\\Fe\end{matrix}\right\} \quad (3)$$

through the combined effect of small amounts of silicon and fluorspar.

In any case, when a white lime slag is used desul-

phurization depends on basicity, temperature and the saturation point of that particular slag for calcium sulphide. It is doubtful whether high sulphur (0.06 to 0.08 per cent) could be removed without the presence of considerable amounts of calcium carbide, but a sulphur content of 0.03 or 0.04 per cent can easily be reduced to 0.02 per cent or below with the white lime slag.

White Carbide Slags

The carbide slag, the most common of electric furnace finishing slags, is preferably composed of lime, coke and fluorspar in the ratio of 6 to 2 to 1, varying slightly with furnace conditions and with the steel made. The slag ingredients are mixed thoroughly on the floor before being charged. Approximately 1 lb. of slag mixture is used for 15 lb. of metal, the larger hot-metal furnaces taking less slag in proportion than the smaller furnaces working on cold scrap. Immediately after removing the oxidizing slag and any necessary recarburization the well mixed slag material is thrown on the bath. In 20 to 30 minutes, with a high temperature, a slight frothing begins around the electrodes and gradually extends to the banks. The slag is in good condition 30 to 40 minutes after being added. It is now only necessary to add lime, coke or spar in small amounts to maintain proper slag conditions until the heat is ready to tap. The gentle boiling or frothing of the bath slowly dies down; about an hour after the slag is in condition it is perfectly quiet. A metal test will show very slight bulging and practically no sparking when deoxidation is complete. Ferrosilicon is now added to give the required analysis and the heat is tapped. With a proper carbide slag, less than 10 per cent of the ferrosilicon is lost, 90 per cent or more alloying with the metal.

The slag when spread on a plate disintegrates slowly in the air to a grayish powder and when moistened with water smells very strongly of acetylene. As shown in Table III, it will contain from 0.5 to 2 per cent carbon, equivalent to 1.40 to 5.6 per cent calcium carbide.

A Disadvantage of the Carbide Slag

The one disadvantage of the carbide slag is the large absorption of carbon by the bath. An extreme case of this absorption was shown by an order of low-silicon steel made at an Eastern plant. Carbon was specified 0.65 or 0.75 per cent and silicon 0.08 per cent or under. In an effort to insure complete deoxidation without the aid of silicon an extra heavy carbide slag was used. Forty-five minutes before tap the bath contained 0.58 per cent carbon. No carbon was added in any form except in the slag-making materials, yet the ladle test showed 0.71 per cent carbon, 0.13 per cent being picked up from the slag in 45 minutes. The steel as poured held 0.027 per cent Si, none being added to the heat, and a thorough inspection of the rolled bars showed the steel to be remarkably free from surface seams and cracks. The slag immediately before tap contained 5.78 per cent calcium carbide.

In average practice, using fair scrap and melting down to retain carbon and manganese, the average absorption of carbon by the metal from the slag is 0.03 to 0.05 per cent. This absorption is nearly constant and is allowed for, as shown in Tables I and II.

The principal advantage of the carbide slag is its intense reducing power, shown by the reactions

$$CaC_2 + 2FeO = CaO + 2CO + 2Fe \quad (4)$$

$$CaC_2 + 2MnO = CaO + 2CO + 2Mn \quad (5)$$

These equations show the end results of some very complicated reactions. By the aid of the calcium carbide the greatest part of the deoxidation takes place during the deoxidizing period exactly when it should and not in the final 15 minutes, aided by a ferro-alloy.

By careless furnace practice the carbide slag may easily become as inefficient as the white lime slag—in fact it may easily turn into a white lime slag through neglect. Atmospheric oxygen coming into the furnace through frequent opening of furnace doors reduces the efficiency and deoxidation power of the slag to a point where it is very little if any better than the white lime slag.

A visual examination of a carbide slag will show the effect of an oxidizing atmosphere. A spoonful of slag is removed from a point midway between the electrodes and the bank, permitted to solidify in the spoon, and then knocked out and examined. On the surface exposed to the air the slag will have the pure white color of lime, while next to the metal of the spoon the dark gray of the carbide will be plainly noticeable.

Deoxidizing With Air-Tight Furnace

An extensive investigation of the plan of deoxidizing with a practically air-tight furnace was undertaken a few years ago in connection with a contract for 600 tons of ingots for 12-in. armor-piercing shells. A 6-ton Heroult furnace was used and the scrap was a mixture of nickel-steel crop ends, chromium-nickel gears and flashings, boiler plate and punchings. Oxidation was carried to completion, the oxidizing slag being removed by hand rabbling. A well-mixed carbide slag was then shoveled into the furnace, and the doors were closed and sealed with fireclay. After 30 minutes one door was opened sufficiently for additions of alloys and further slag material, and then sealed again. This practice was followed for about 100 heats. Steel was poured into regulation shell molds without sinkheads. On stripping, the surface of the ingots was in every case found to be free from pits, and the top surface showed complete absence of oxidation bubbles. A report from the forger stated that every heat forged perfectly, all shells passing inspection easily. Physical tests were in every case satisfactory and usually superior to requirements.

Every heat tapped had a slag that was intensely reducing. Although slag analyses were not made, each ladle slag after dumping into the pit and cooling with water gave an odor of acetylene that could be detected within a radius of 50 ft.

Carbon absorption was calculated at 0.06 per cent, each heat being tapped on 0.46 to 0.48 per cent to meet a specification of 0.50 to 0.60 per cent.

It is unquestionable that the exclusion of atmospheric oxygen from the furnace produces a more completely deoxidized metal and leads to better slag conditions. It is also beyond possibility of doubt that deoxidation in the furnace by aid of a slag high in calcium carbide produces a better steel more consistently than a simple treatment with a highly basic lime slag and subsequent deoxidation by a ferro-alloy before tapping.

The amount of oxides in the metal determines the amount of calcium carbide that must be maintained in the slag. By carrying a simple lime slag, a charge of muck bar and washed metal and rolling mill crop ends may be deoxidized to make a thoroughly sound steel. By having 1.0 to 2.0 per cent calcium carbide, a steel melted with partial oxidation, the carbon and manganese

remaining to a large extent in the metal, will be deoxidized satisfactorily. But a steel containing a large amount of oxides, when melted low in carbon by the use of ore or on a metal duplexed from an open-hearth furnace and not partly deoxidized in that furnace, requires a very heavy carbide slag, preferably one containing 2 to 5 per cent calcium carbide.

For general purposes when making miscellaneous alloy and tool steels from ordinary scrap, the best furnace practice for a consistently satisfactory product, is:

(1) Melt to retain part of the carbon and manganese; remove phosphorus by means of a very basic slag, omitting ore or other oxide and using clean scrap.

(2) Unless absolutely necessary do not recarburize on the bare metal after the first slag has been removed. If a small amount of carburization is necessary after all alloy additions, use clean pig iron or washed metal. In an emergency, run the electrodes down into the bath.

(3) Mix the deoxidizing slag materials thoroughly, using 5 or 6 parts of burnt lime, 2 parts of powdered coke and about 1 part of clean gravel fluorspar, and add 1 lb. of this mixture for 15 to 18 lb. of metal immediately after the complete removal of the first slag. When melting clean scrap the amount may be reduced to 1 lb. of slag for each 25 lb. of metal.

(4) Use high power for at least 30 minutes, until frothing of the slag is gentle and uniform over the whole bath.

(5) Exclude atmospheric oxygen as much as possible during the deoxidizing period.

(6) With these conditions present and using a scrap not exceeding 0.04 or 0.05 per cent sulphur, desulphurization will proceed automatically to a residual of 0.015 per cent or lower.

Desulphurization with a strong carbide slag proceeds according to the reaction

$$2CaO + CaC_2 + 3\left\{\begin{matrix}MnS\\FeS\end{matrix}\right\} = 3CaS + 2CO + 3\left\{\begin{matrix}Mn\\Fe\end{matrix}\right\} \quad (6)$$

This reaction, too, is the result of more complicated reactions and is generally in conjunction with reaction (1). Reactions (2) and (3) likewise occur when carbide is present, but are secondary in importance to reaction (6).

Many variables influence the desulphurizing power of the carbide slag, although this slag is much more sure in its action than the white lime slag. In order to have much carbide in the slag, the temperature must be high; therefore desulphurization proceeds rapidly. Likewise the carbide slag is always extremely basic. As before stated, it has been proved by countless trials that fluorspar is a distinct aid in desulphurization and in this respect is much superior to silica sand for slag making. Carbide slag saturated with calcium sulphide runs slightly higher in S as the temperature, basicity and amount of calcium carbide increase. It has been possible at times when working with slags very high in carbide to have these hold as much as 4.50 per cent calcium sulphide; this, however, is exceptional, 3.5 per cent saturating the average slag.

A peculiarity of carbide slags that has been largely overlooked by metallurgists, is that the efficiency of the slag as a *deoxidizing* agent decreases rapidly as the saturation point of the slag for calcium sulphide is approached, and this point is easily approached when the lime and coke used both contain up to 1 per cent sulphur. For this reason low-sulphur lime and coke should be used for the slag and a scrap base containing more than 0.05 per cent sulphur should be avoided, if the steel is to be sound, both completely deoxidized and desulphurized.

As one-tenth of the sulphur, sometimes even more, is removed in melting and oxidizing (see Table II), the deoxidizing slag must remove about 0.03 per cent—more than half the original sulphur. This can be done easily with a fairly pure slag, without impairing its efficiency as a deoxidizer.

A peculiar feature, at present not well understood, is the decreased power of a strong carbide slag for removing sulphur when the furnace is kept nearly air tight. In the 600-ton order above mentioned, in which a thoroughly sound and nearly perfectly deoxidized product was attained, in every case without exception the carbide slag removed less than one-third the sulphur, whereas in average practice with no precautions to exclude atmospheric oxygen from the furnace (Table II) sulphur losses amount to 70 per cent and often reach 80 per cent. The scrap charged for the shell steel contained an average of 0.03 to 0.04 per cent sulphur; allowing 10 per cent of this to be removed in the oxidizing period, it is readily seen that the carbide slag absorbed very little, since the analysis of the 100 heats showed sulphur contents of 0.023 to 0.031 per cent.

It may be conceded that steel containing 0.03 per cent sulphur is exactly as good as if the sulphur content were 0.015 per cent. The amount of manganese sulphide present with the higher sulphur is so small and in good steel is so well distributed that possibility of harm from this source is nil. Far more harm and injury may be done by attempting to reduce the sulphur to 0.015 per cent at a sacrifice of complete deoxidation.

Desulphurization vs. Deoxidation

Three things are possible in the deoxidizing period in the Heroult furnace: (1) Desulphurization without thorough deoxidation. (2) Thorough deoxidation with little desulphurization. (3) Thorough deoxidation with complete desulphurization.

The first condition exists when a very basic lime slag containing no calcium carbide is used; the resulting steel is not good, even if the sulphur is reduced to a trace. Practically all of the deoxidation must be carried out by means of ferro-alloys added at the end of the heat.

The second condition prevails when a very basic slag containing considerable calcium carbide is used in an air-tight furnace; an exceptionally sound steel is regularly and consistently obtained, a steel free from blowholes and slag inclusions but only a small percentage of the sulphur has been removed. This practice is to be recommended, however, in preference to the first.

The third condition is difficult to realize in practice; yes, doubly difficult, since the average melter has been educated to believe that deoxidation is secondary in importance to desulphurization, the very opposite to the truth. This third condition is met partly by a strongly reducing carbide slag and by keeping the slag strongly reducing by further additions of lime and coke from time to time. While the doors are not sealed tight, they are kept closed as much as possible so that the carbide present will not be oxidized much by the air. Table II gives the complete history of a heat of carbon

chisel steel made from a poor grade of scrap and oxidized completely, the bath recarburized and deoxidized by means of an average carbide slag. The heat represents ordinary practice and is neither very good nor very bad. The heat was poured into 9 x 9-in. ingots, the ingots were chipped, reheated and roughed to 2½-in. square billets. The billets were chipped but not pickled. Finished rolling was into mill length ¾, ⅞ and 1 in. octagon. Approximately 15 per cent of the finished bars were scrapped on account of seams.

In contrast to this, Table I shows the history of a heat of first-class ball steel. This heat was also poured into 9 x 9-in. ingots. The ingots were chipped, reheated and roughed to 4½-in. gothics. The top and bottom discard was nicked by the hot saw and fractured. The gothic billets were pickled and chipped, very little chipping being necessary, and were finished to 2-in. and 2½-in. rounds, mill lengths. Less than 5 per cent of the heat was rejected for surface defects on inspection.

Good Steel Requires Thorough Deoxidation

The author has seen 40-ton heats of chromium-nickel steel for navy guns, after 4 hours' electric refining, that were chemically, physically and microscopically the finest steel possible to make by any process. On the other hand, he has watched a melter throw shot aluminum by the shovelful into the ladle of a 20-ton electric furnace heat to quiet it enough to pour. He has seen 6-ton heats, made from the best-selected open-hearth and electric furnace scrap, that would scarcely stay in the molds and the cross-section of the ingots resembled a piece of Swiss cheese. On the other hand, he has seen 6-ton heats case-hardening gear steel of an analysis 0.08 to 16 per cent carbon, 3.50 per cent nickel and 2.00 per cent chromium, that rolled into a 100 per cent perfect product.

Whether duplex is better than cold-scrap electric steel has been argued pro and con for the past 10 years, the controversy waxing hottest during the war. It may be said once and for all that the quality of electric steel does not depend upon the base used; good scrap, bad scrap, molten open-hearth metal, molten bessemer metal, whether melted in 1-ton or 40-ton lots may all be refined and deoxidized completely and thoroughly with the proper slag made under the proper conditions and handled by men who know how. Naturally, the more nearly the steel is deoxidized before the final electric furnace slag is applied the easier deoxidation will be, but the complete deoxidation in any case is merely a matter of correct slag conditions for the proper time.

Charleston, W. Va.

Italy Considering Limitations on the Exportation of Metals and Waste Metals

The recent decree providing that the customs officials at Italian frontiers and seaports may permit the exportation of lead, copper, manganese and zinc metals, lead residues, ashes of iron pyrites, waste copper, tin, zinc, brass, bronze, aluminum and nickel is not working satisfactorily, reports the special correspondent of Chemical & Metallurgical Engineering. It has led to the exportation of large quantities of these products to Germany, Czechoslovakia, Austria and other countries, to the deprivation of home producers. Accordingly a petition has been presented to the Minister of Industries, setting forth the damage already suffered and likely to be suffered later and asking that the decree be abrogated for the present.

Oil and Coal as Plastic Fuels

A new combination of oil and coal in a plastic fuel which suggests large possibilities was recently described* by Walter E. Trent of Washington, D. C. This was the first public discussion by Mr. Trent of the process on which he has been working for several years and on which the Bureau of Mines has been co-operating for some time past. He described further the commercial possibilities of the process, some features of which were given in Chemical & Metallurgical Engineering of Aug. 3, 1921, p. 182.

That coal, oil and water can be premixed in just the right proportions for water-gas manufacture and can be simultaneously introduced into the generator in intimate contact with one another is one of the most interesting possibilities suggested by Mr. Trent's work. The process is based upon the reaction by the coal and oil which follows mixing oil with a suspension of very finely ground coal in water. The coal is ground wet and to the suspension oil is added equal to about 30 to 40 per cent of the weight of the carbonaceous matter present. The oil and coal agglomerate into a plastic mass which is very easily separated from the water and ash.

Commercial Scale Plant in Operation

Mr. Trent has built a commercial-scale plant at the former yards of the Virginia Shipbuilding Corporation, Alexandria, Va., where the layout contemplates a completed plant to handle 1,000 tons per day of raw coal. At present the first of four units having a daily capacity of about 250 tons is the only one complete. Mr. Trent is operating this plant regularly on a variety of coals, including many experimental tests of 50-ton and larger lots to determine the suitability for use with his process.

A number of experiments have been made on production of city gas from the amalgam both by distilling this in ordinary coal-gas retorts and by treatment of it in water-gas machines. Apparently gas, byproduct and coke yields are very satisfactory even with relatively inferior coals. The results in water-gas equipment have been equally encouraging, Mr. Trent reports. Tests have also been conducted on a limited scale as to the application of the amalgam for manufacture of producer gas. Mr. Trent states that by this means very good yields of a producer gas approximating 400 B.t.u. per cu.ft. will probably be obtainable.

The plastic material can be burned on certain types of stoking and boiler equipment, and further tests along these particular lines are now under way. Considerable use of the material as a domestic fuel is also being practiced locally in Alexandria, but Mr. Trent points out that the fuel, though otherwise very satisfactory, is certainly exceedingly dirty for domestic use and on this score quite objectionable in many circumstances.

Mr. Trent contemplates experimentation on the low-temperature distillation of the amalgam by special methods now under development. By this means he hopes to recover not only the original oils used but also the byproducts from the coal and to make smokeless fuels in the form of almost ashless briquets. This has been done on a small scale, but the large-scale work is not yet under way. The Bureau of Mines has made a study of certain of the fundamentals involved in the distillation of these amalgams.[1]

Low-Temperature Carbonization in England

A Survey of British Practice in the Carbonization of Coal at Low Temperatures and a Detailed Description of the Construction and Operation of the Experimental Plant of Low-Temperature Carbonisation, Ltd., at Barugh, Near Barnsley

BY DAVID BROWNLIE
Manager and Director, Brownlie & Green, Ltd.

THE general principles of the process of low-temperature carbonization are already well known and many articles and papers have been published on the subject, both in America and in Europe. The essential facts of the three processes of carbonization as they are carried out in Great Britain are shown in Table I.

It may seem a simple matter to carbonize coal at a lower temperature, but in practice the difficulties are extraordinarily complicated. When coal is heated it softens and swells and the maximum expansion seems to be at about the temperature of 550 deg C. (1,022 deg. F.). The consequence is that in an ordinary retort the residue is wedged tight in the retort as a slightly viscous mass and cannot be withdrawn. In high-temperature carbonization this trouble does not exist, because as the temperature increases the viscous materials are decomposed and the coke contracts again in volume, so that it comes out of the retorts without trouble. When the hot coke is taken out of the coke ovens into the air it gives a short flash of flame and is then quenched with cold water, retaining its shape and texture. If the hot residue from the low-temperature process is handled in this way, it blazes furiously because of the higher percentage of volatile matter (9 to 10 per cent) present, and when quenched with water it cracks up, loses its texture and eventually falls to "breeze."

TABLE I. YIELDS FROM ONE TON OF AVERAGE COAL (25-35 PER CENT VOLATILE MATTER) IN THREE PROCESSES OF CARBONIZATION (BRITISH PRACTICE)

Process	Low-Temperature Carbonization	High-Temperature Carbonization	
		Gas Works	Coke Ovens
Temperature of carbonization	1,000 deg. F.	About 1,800 deg. F.	About 1,800 deg. F.
Gas	6,000-6,500 cu.ft. of rich gas, 700-750 B.t.u. per cu.ft.	12,000 cu.ft. of medium quality (city) gas 550 B.t.u. per cu.ft.	11,500 cu.ft. of poor quality (coke-oven gas 450 B.t.u. per cu.ft.
Liquid	20 gal. of oil (fractionated to 3 gal. motor spirit, 8-9 gal. Diesel oil and 8-9 gal. lubricating oil	10 gal. coal tar	8 gal. coal tar
Sulphate of ammonia	15 lb.	25 lb.	28 lb.
Residue in retort	1,568 lb. of smokeless fuel (9-10 per cent volatile matter)	1,512 lb. of soft coke (about 1 per cent volatile matter)	1,568-1,624 lb. of hard metallurgical coke (less than ½ per cent volatile matter)

DIFFICULT PROBLEMS IN RETORT CONSTRUCTION

As regards the material of the retorts, the ordinary firebrick retort is porous at the high temperature to the gas formed, which then burns outside the retorts. This does not matter much in high-temperature processes except that 5 per cent or so of the gas is wasted, but for low-temperature carbonization it is fatal, since this gas burning in the retort flues alters and raises the temperature, so that all control is lost, in addition, of course, to the loss of rich gas.

Another difficulty is that coal is a bad conductor of heat, and to submit every portion of a given mass of coal to a definite temperature of 550 deg. C. (1,022 deg. F.) means that the carbonization must take place in comparatively thin layers.

It is often stated that if low-temperature carbonization is required, all that is necessary to do is to lower the temperature of the ordinary retorts. The result of this is to form coke on the outside layers in the retort and practically unchanged coal inside. A mixture of half-baked coal and coke is not the product desired, which is a homogeneous product in a peculiar physical condition of porosity and texture.

One of the most difficult problems to solve was the material of the retorts. The difficulty with cast iron or mild steel is that when subjected to a continuous red heat it begins, almost in a few weeks, to waste away and also to "creep" or alter its shape. If cast iron could be used, it would be an ideal material, because it is a good conductor of heat, absolutely non-porous to the gas produced in the process, and can easily be cast accurately to any dimensions required.

In the early days of the gas industry in Great Britain, when the wear and tear on the retorts was much more severe than for low-temperature carbonization, although the temperature in those days certainly not as high as in the present gas industry, cast-iron retorts were used and usually lasted several years. This probably led to Parker's persevering tests with cast iron. The attempts were finally abandoned, however, and firebrick retorts were constructed, on the original advice of Prof.

FIG. 1. GENERAL VIEW OF EXPERIMENTAL PLANT AT BARUGH, NEAR BARNSLEY

V. B. Lewes. It is very likely, however, in the future that cast iron may be experimented with again in view of present research into the constitution of metals.

Experimental Plant at Barugh, Near Barnsley

With this brief outline of some of the problems presented by the low-temperature process, it is the intention of the writer to describe in considerable detail the experimental plant of Low Temperature Carbonisation, Ltd., which is located at Barugh, near Barnsley, in the center of the Yorkshire coalfields. This plant is in reality a good-sized works, as may be from Fig. 1. It consists of a unit of twenty retorts with a capacity of about 30 tons of coal a day, and with a complete recovery plant, coal washers, scrubbers, benzene-rectifying house, gasometers, producer gas plant, power station, etc., sufficient to handle the products from four or five times the present number of retorts. However,

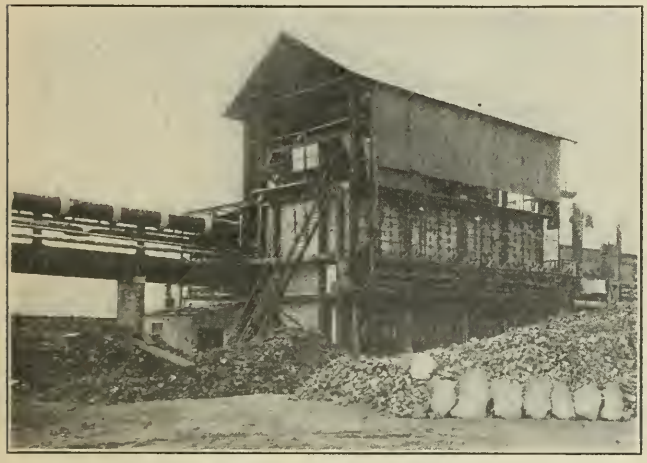

FIG. 2. VIEW OF RETORT HOUSE

since the whole process depends on the retorts, the company decided to confine itself to one unit of twenty retorts until complete success was obtained, as the erection of future units of retorts is a simple matter.

Each of the twenty retorts consists of a coal hopper at the top, a carbonizing retort beneath, and below this retort, a cooling retort, as shown in detail in Figs. 2 and 3.

The coal to be carbonized, which has first been washed, is fed into the hoppers, and each hopper holds exactly one charge of coal. These hoppers can easily be supplied mechanically with the coal by means of a horizontal scraper or other conveyor, so that when one hopper is emptied it is immediately refilled automatically. At present these hoppers are filled by small hand-propelled trucks, but this is simply a minor detail to be remedied in a larger scale installation. The charge, which consists of 10 cwt. (1,120 lb.) then lies in the hopper for 7 to 8 hours while the charge below in the retorts is being carbonized. During this time is becomes warmed by the heat of the retort, serving the double purpose of preventing heat loss from the retorts and warming the charge so that it loses moisture and does no damage to the red hot retort when the time comes for it to be dropped down. Between the bottom of this hopper and the top of the retort is a heavy rotary door or valve, operated by hand by means of a long lever, as shown in Fig. 4. When the retort below has been emptied, the attendant pulls the lever and lets the warmed charge of coal in the hopper fall into the hot retort. The retorts are of the vertical pattern, the inside dimension of each retort being about 9 ft. 0 in. x 6 ft. 6 in. x 11 in. They are built of firebrick cemented with fireclay into one unit of twenty retorts complete with all the necessary flues. All future plants, no matter how large, will be an aggregation of these standard units of twenty retorts each.

Description of Retorts

Inside each retort are two vertical perforated cast-iron plates extending for practically the entire height of the retort; the distance between these plates is about 4 to 5 in. The coal falls down into the retort from the hopper above, and fills each of the two empty spaces between the side of the retorts and the plates, but it cannot fall between the plates. That is to say, when full, each retort contains two vertical masses of coal 9 ft. 0 in. x 6 ft. 6 in. x 3 to 3½ in. thick, separated by two perforated iron plates, and an empty space 4 to 5 in. wide between the plates.

Heating the Retorts

The retorts are heated by a series of burners on the outside (as shown in Fig. 2) supplied by producer gas (or if necessary by the rich gas from the process); the burner flues between retorts are situated horizontally one above the other. The exit flue gases pass downward at the end of each horizontal flue, and into a similar flue below, regenerated at each flue by supplementary burners until the bottom of the retort is reached, where they then pass through the "recuperators" to the chimney exit of the plant. The fresh cold air supply for the burners passes through these recuperators and is thus preheated. The amount of heat lost by the whole battery of retorts is remarkably small, and the complete installation has a heat efficiency of about 75 per cent. The heat required to carbonize 1 ton of coal is about 2,500,000 B.t.u., equivalent to about 10 per cent of the coal—that is 2 cwt. (224 lb.) of coal or coke per ton. In a modern coke oven the heat required to carbonize 1 ton of coal is about 3,000,000 B.t.u. The burners are provided with spy holes in the brickwork, and the necessary temperature of about 650 deg. C. (1,202 deg. F.) in the flue outside, equivalent to about 550 deg. C. (1,022 deg. F.) inside the retort, can be obtained by adjusting the gas supply in accordance with the color of the flame. The latter operation is based on experience gained originally by the aid of pyrometers.

The exact temperature to use depends to some extent on the nature of the fuel required, the quality of the coal used and the yield of different products (depending on the market prices at the moment), but the figures previously given are about the average. The carbonization then proceeds for 8 hours, although it is possible that this time will be cut down in the future to 7 hours, or perhaps even to 6. To prevent the gas leakage through the sides of the retort, the top of the retort communicating with the empty space between the two vertical plates is connected direct to the exhausters, so that there is a slight suction down the center of the retort. Because of the perforated plates practically every portion of the heated mass of coal (in thin layers) is in direct communication with the suction space. Consequently, the distillation products, all gaseous at the temperature of 550 deg. C. (1,022 deg. F.) pass directly out of the coal into this central chamber through the perforations and up out of the retort. They have not to pass, as with an ordinary retort.

through a mass of hot coal a number of feet in height, which partly decomposes the products and at the same time causes a pressure in the retort, thus increasing the tendency for these products to pass through the fireclay sides. This objectionable tendency in an ordinary retort is helped also by the chimney suction in the burner chambers outside of the retorts, and any suction at the top is lost after passing a few inches down into the mass of coal.

With these retorts containing the perforated plates, however, the suction is applied at once to every portion of the mass, and no gas at all passes through the retorts the reverse way into the flues. The gaseous products pass out of the retorts into the recovery portion of the plant in the usual way, and the after-treatment is the same as that of a coke oven.

Discharging the Hot Fuel

When the carbonization is completed, the attendant, by means of a hand lever, opens a heavy horizontal circular or rotary door in the bottom of the retort and by means of another handle on the top actuates a simple mechanism which causes the two perforated iron plates to come close together inside the retort with a slight shearing motion, so as to obviate any tendency of the residue to stick in the perforations. The consequence is there is now a clear space of 2 in. or so all down one side of the huge slabs of hot fuel and the pressure due to the expanded mass no longer exists. The two slabs thus fall out of the retort bodily without the slightest trouble. Underneath each retort is a special water-jacketed cooling chamber constructed of steel, of exactly the same internal dimensions as the retorts. These steel cooling chambers are in reality waste-heat boilers, the jackets being able to work at 100-lb. steam pressure. Water is circulated through these jackets, and the hot slabs of fuel, in the almost complete absence of air, lie in these cooling vessels while giving up their heat to the cooling water. In practice the temperature of the water in the jackets is generally over 212 deg. F. and steam is generated at about 5 lb. pressure. These jackets are also arranged to be heated by the exit gases from the recuperators which come in contact with the surface of the jackets at about 300 deg. C. (572 deg. F.) and finally leave at about 130 deg. C. (266 deg. F.). The steam raised in the exit chimney of the plant is employed in making the producer gas, in distilling the tar and in other useful operations. The vertical side of these cooling chambers is composed of a door, which is opened, and the fuel pulled out by hand rakes on to the sloping cement floor (see Fig. 5) and slides down to the store or direct into trucks, being a hard, porous, compact solid, only warm to the hand. The product is so hard that it is superior in this respect to briquets. The pieces are thrown into railway cars in the same manner as coal, and travel quite as well as coal itself; the breeze formed is infinitesimal. Thus the product is now arriving regularly at Marylebone station (London) from Barnsley, 200 miles away, in perfect condition.

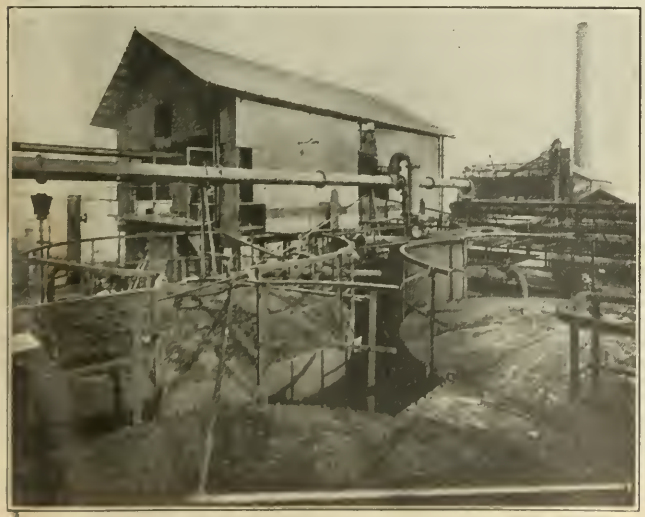

FIG. 9. RETORT HOUSE, WITH STORAGE TANKS FOR OIL IN FOREGROUND

Economic Considerations

The cost of labor and attendance in working a complete low-temperature carbonization plant is about the same as that of a coke-oven plant. The whole of the recovery side of the plant, constituting about 60 per cent of a complete low-temperature installation, is practically identical with that of existing high-temperature carbonization processes. The balance sheet of the whole process is very satisfactory, even on a conservative estimate of the market value of the various byproducts of gas, motor spirit, Diesel oil, lubricating oil and sulphate of ammonia produced, especially since the fuel can replace coal in practically any operation, household or industrial.

The coal used, while it must be of the dimensions of ordinary slack, can be of the most varied composition. A remarkable achievement is that two parts of non-coking coal can be mixed with one part of coking coal and used to produce a very satisfactory smokeless fuel. The importance of this will be obvious, as it means that practically all the coals of Great Britain can be subjected to this process. Another noteworthy achievement is that a large proportion of fine slack and dust, now practically a waste product of the collieries, can also be utilized, and the importance of this to the colliery industry can hardly be overestimated.

Gas. As already noted, the yield of gas is considerably lower, 6,000 to 6,500 cu.ft. per ton, as compared with 12,000 cu.ft. in the average high-temperature gas works. However, the gas is richer, since it yields about 700 to 750 B.t.u. per cu.ft., as against 550 B.t.u. for city gas and 450 B.t.u. for coke-oven gas. Naturally the composition of the gas depends on the quality of the coal used in the low-temperature retorts, but as compared with city gas it is richer in methane and olefines and has a much higher illuminating power. Roughly speaking, with average coal of about 30 per cent volatile matter, the composition of low-temperature gas is about 27½ per cent hydrogen, 48 per cent methane, 10 per cent paraffine hydrocarbons, 3 per cent olefines, 7½ per cent CO, 2½ per cent CO_2, and 1½ per cent nitrogen.

Oil. The oil from the process resembles crude oil in appearance and is quite different in composition from coal tar. It has a specific gravity of about 1.06 and contains less than 1 per cent of free carbon, while coal tar has a specific gravity of about 1.18 with a large amount of free carbon, generally over 6 per cent, which is caused by the excessive decomposition resulting from the higher proportion of the simpler and lower organic compounds of the benzene and cresol groups, with no phenol and an almost entire absence of the higher hydrocarbons of the type of naphthalene, anthracene, carbazol, etc.; the percentage of pitch is also much less. About 45 per cent of the low-temperature oil comes

over between 160 and 300 deg. F., while with coal tar the figure is only about 12 to 14 per cent.

It is curious that cresols, which are very valuable for wood preservatives, are present in large quantities in this oil, corresponding to about 3 gal. per ton of coal. In coal tar the chief product of this class is phenol or carbolic acid, and there is very much less cresol. Naphthalene is entirely absent in low-temperature oil and present in large quantities, 5 to 10 per cent, in coal tar, which reduces the value of the latter in comparison.

The large amount of motor spirit produced, about 2 to 3 gal. to the ton of coal, depending on the quality, is a very valuable product. It has a particularly low freezing point, about —50 deg. F., whereas benzene is about +40 deg. F.

The fraction above 300 deg. F. amounts to about 42 per cent. It is then treated by steam, whereby valuable lubricating oils are removed, leaving about 34 per cent of pitch; and from this further heavy lubricating products such as vaseline can be extracted. In this pitch residue there is less than 6 per cent of free carbon, whereas in the ordinary pitch from coal tar there is a very large amount, generally about 28 per cent.

A large portion of the oil, after removing the pitch, can be used direct as Diesel oil, corresponding to 8 or 9 gal. per ton. It works perfectly, starting from cold and giving results of about 0.5 to 0.55 lb. of oil per brake horsepower.

Sulphate of Ammonia. This is extracted from the gas in the usual way by means of sulphuric acid, the yield being about 15 lb. per ton of coal, less than the high-temperature carbonization processes because the decomposition of the nitrogenous matter in the coal is less drastic due to the lower temperature.

Smokeless Fuel. This is a hard, crisp and porous solid, which contains about 8 to 9 per cent of volatile matter. The actual B.t.u. is about the same as the coal from which it is manufactured, but the effective heating value is for many uses higher because of the emission of much more radiant heat in the burning. Like coke, it is absolutely smokeless. Black smoke is of course due to the escape of unburned matter, as the rate of combustion is too slow to complete the oxidation before the smoke can escape. For this reason anthracite, which contains very little volatile matter, and coke, which contains none at all, are absolutely smokeless. As the fuel from the low-temperature process is also smokeless, it would appear that any amount of volatile matter up to about 12 per cent can be burned without trouble, but when over this, black smoke begins to appear. It is also clean and not dusty like coal, and ignites almost as easily as coal, unlike coke, which is very difficult to light. Like coke it too is a highly efficient fuel for steam generation because of the high radiant heat.'

2 Austin Friars,
London, E. C., 2.

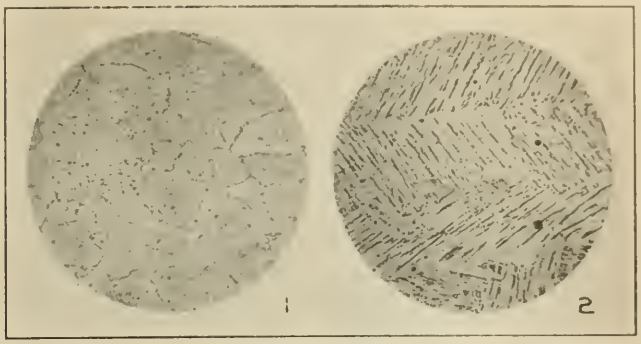
Tests of Rubber Goods

Standard methods of testing rubber goods of all sorts are described in the new (fourth) edition of Circular 38 of the Bureau of Standards, which is now available from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 20c. per copy. The circular also includes a brief discussion of crude rubber and the manufacture of rubber goods, both the composition and the methods of manufacture.

Oxygen and Nitrogen in Welds*

By S. W. Miller

IT IS known that a weld made with a low-carbon steel wire for welding rod is usually an over-oxidized steel casting, and its maximum strength cannot be in excess of 52,000 lb. per square inch. If nickel steel wire (S.A.E. 2320) is used, however, its strength can be kept up to 58,000 lb. per square inch by careful and competent workmen, and its state of oxidation is much less. This seems to be due to the formation during welding of a tough viscous slag, which is probably due to the formation of nickel oxide. This coating on the weld is very thin, but seems to be sufficient largely to protect the metal from the action of the air. Whatever the cause may be, the microstructure of the weld



FIGS. 1 AND 2.

Fig. 1. Gas weld in sheet steel. Notice large grain size due to heat. Small dots are ferrous oxide. A few particles of carbide at grain boundaries. Etched. ×200.

Fig. 2. View in weld made with 0.20 carbon, 3½ per cent nickel steel wire. The carbon is largely preserved by the nickel, making the weld pearlitic and stronger than one made with ordinary wire. ×100.

shows it to be much more free from ferrous oxide than ordinary weld metal. (Compare Figs. 1 and 2.) Any material will answer that will give equal results. But nickel steel is readily obtainable and, until other alloys are found, I feel that nickel steel should be used for important work.

It is just as necessary to have high quality in the base metal as it is in the welding rod, and I might say at the beginning that I have never found a bad welding steel that was not full of sonims, nor a good welding steel that was not free from them, except in one or two instances. I believe it is possible to make a bad welding steel by improperly annealing good material, especially in sheet, where the effect of oxidizing atmosphere is much greater in proportion than in plate, because of the thinness. The effect is to make the material brittle, presumably by permitting the oxygen to penetrate the grain boundaries, being in effect an incipient burning. It has been shown that by heating in a reducing atmosphere at a temperature below the Ac_1 point the brittleness was removed, which would seem to show that oxide films at the grain boundaries caused the trouble.

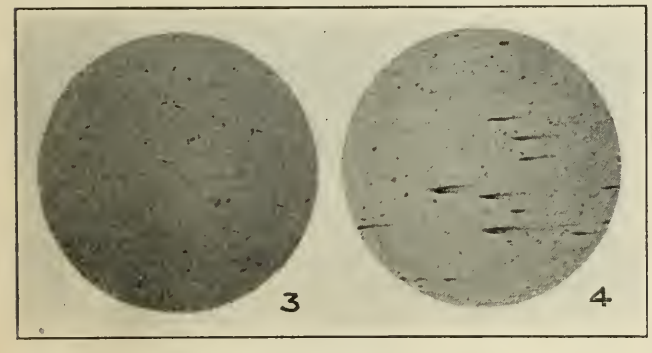
The nature of the non-metallic impurities that cause trouble in welding I am not sure of, because they are usually very small, but as the metal just around them seems to be porous to a greater or less extent, it would seem that they must be oxides or silicates. It is also quite probable that the porous part is filled with gases, because bad welding material spits when it is heated to the welding point, indicating that gas has been

*Extracts from a paper read before the American Iron and Steel Institute, Nov. 18, 1921.

formed in some way. It is also noticeable that in preparing a specimen for the microscope the later grindings, if done on soft cloth, remove the material around the sonims and give the unetched section the appearance of being spotted with a lot of comet tails, which of course are much larger than the actual size of the particles of impurities.

I think it is perfectly safe to say that the microscope will always determine whether a steel will weld properly (see Figs. 3 and 4), except where it has been put through an annealing process which would damage it at the grain boundaries. I also feel that chemical analysis shows nothing of the welding qualities within wide limits, unless the steel is badly off.

The microscope shows better than any other instrument the nature of the defects in welds, and when this is known, and not until then, precautions can be taken to avoid them. Generally speaking, there are two avoidable defects, which are in reality one—first, lack of fusion in the weld metal itself. (Fig. 5.) The tendency in welding steel is to underheat the plate, because it is much heavier in section than the welding wire, in which case the melted wire may fall into the V without being fused to it. The same thing may happen in the weld. When this occurs there is a thin film of oxide between the two layers of metal, and this of course destroys the strength of the piece. In addition to this there is the oxidizing action of the water vapor in the gas welding flame and that of the air on the finely divided metal passing through the electric arc. If the gas welding flame be not properly adjusted, or if the torch be of poor design, there is the additional possibility of free oxygen being present and causing



FIGS. 3 AND 4.
Fig. 3. Good welding steel. Sonims few and small. ×35
Fig. 4. Poor welding steel. Sonims larger and more numerous than in Fig. 3. ×35.

serious trouble. An improperly made weld will show streaks of oxide or other impurities which are frequently very small and thin, and yet the first evidence of distortion of such a weld is at these defects, just as the first evidence of distortion in a piece of steel is at similar defects. During the welding operation these defects appear as bright white spots or streaks in the case of gas welding, which can be floated to the surface and removed. In the case of electric welding this is not possible, except to a limited extent, because whatever impurity is in the electrode must go into the weld. The films or streaks referred to are frequently clearly visible under the microscope, but many times rupture occurs at the grain boundaries in both gas and electric welds, where there are no evidences of any films even at the highest power of the microscope. (Fig. 6.) These ruptures must be at the austenite grain boundaries, because to them the impurities are rejected during the solidification of the metal. In cases of welds where it is possible to distinguish between the gamma and the alpha grain boundaries, as is possible when there is much pearlite, I have never seen a case of rupture at the alpha boundaries. This would seem to be quite natural,

FIGS. 5 AND 6.
Fig. 5. Defective gas weld, full of laps. ×200.
Fig. 6. Electric weld. Grain boundary rupture; no evidence of defect before straining. ×200.

because the alpha grains are formed by the recrystallization of the gamma grains, and if there be any impurities at the gamma grain boundaries it is not possible for one grain to grow at the expense of another one past such impurities.

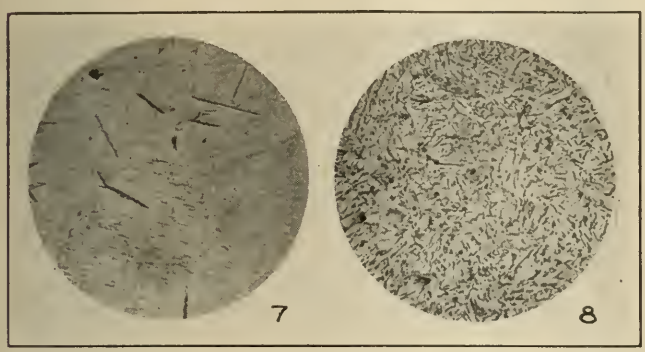
It would scarcely be expected that any ordinary heat-treatment would alter the character of the ruptures in welds, and if defective welds were heated in an oxidizing atmosphere it might be expected that they would become more brittle. Such tests as I have made indicate that this is true. On the other hand, I have found that electric welds which were very brittle as made were notably improved by heating several hours in a strongly reducing atmosphere at a temperature of about 600 deg. C. This would indicate that the difficulty is one of oxide.

Prevention of Oxidation

Oxidation should evidently be less severe in the case of gas welds than in electric welds. First, because the temperature is not so high, and second, because of the protecting influence of the envelope flame, which is composed of hydrogen and CO burning to water and CO_2. In the electric arc the temperature is very high, and the metal passing over the electrode to the weld is very finely divided, with naturally great oxidation. It will appear clear that if the melted metal could be covered with a protecting slag, oxidation would be much lessened. This has been done for a number of years in electric welding by coating the electrodes with compositions of various kinds which produce slags of various viscosities. If the slag is too viscous, it may be entangled in the weld, weakening it, and if too thin, it will not protect the metal; but it is a fact that electrodes of this type when properly used give a sounder weld than electrodes made of bare wire. With gas welding no organized attempt has been made to provide such a slag covering. Naturally with the lower temperature a thinner slag will be necessary, but there is also to counteract this the blast from the flame, which has a velocity of about 375 ft. per second at the exit from the tip, which tends to blow away the slag and to leave the metal exposed. It is rather curious that nickel steel welding rod seems to provide a very thin slag. It is entirely probable that before best results will be ob-

tained with gas welding it will be necessary to provide a properly coated welding wire. It might be mentioned incidentally that in the case of non-ferrous metals such as brass and bronze, much sounder welds are produced when the welding material contains slag-forming constituents and when flux is sparingly used than when other conditions prevail. This would naturally be expected, because of the well-known fact that a clean surface of melted metal permits the absorption of gases which are given out during solidification, causing porosity.

Welding rods are low in carbon (that for gas welding having about 0.06 per cent and that for electric welding about 0.15 per cent[1]), yet there is always a loss of carbon due to the heat, so that the weld made with



FIGS. 7 AND 8.

Fig. 7. Nitrogenized iron. Primary and secondary plates of iron nitride. The primary ones (large) appear to lie along Neumann directions, while the secondary ones (small) appear to be parallel to the intersection of an octohedron by a cube face in two grains, and in the third (upper left corner) along intersections of an octohedron with dodecahedral planes; the larger plates do not appear where the small ones are. Etched with picric acid. ×200.

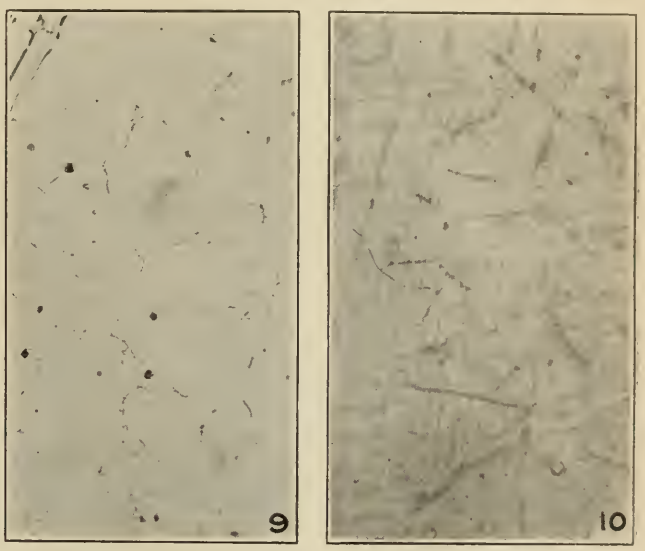
Fig. 8. Electric weld in ¾-in. plate. View in weld. Many iron nitride plates, small in size because of rapid cooling.

such materials does not contain over about 0.03 or 0.04 per cent of carbon. Manganese and silicon are also lost, but, as would be expected, the phosphorus and sulphur do not change. In the case of heavy welding the loss of the above elements is less near the V than in the center of the weld, as there is some interchange of the elements between the weld metal and base metal, so that in sampling a weld for chemical analysis care should be taken to keep away from the edge of the V, unless proper allowance is made.

While there is a loss of some elements, there is a gain in both oxygen and nitrogen. Nitrogen in both gas and electric welding comes from the air, while the oxygen probably also partly comes from the water vapor in the envelope flame in the case of gas welding. It is generally believed that molecular nitrogen has but small affinity for iron at even high temperatures, and this is doubtless true. On the other hand, iron ordinarily combines with nitrogen in the nascent condition at 1,400 deg. F., as has been proved by numerous tests.

There has been much discussion as to the effect of nitrogen on steel, some taking the position that it makes steel brittle and others that it has very little if any effect. The presence of nitrogen as nitride can be quite accurately determined by chemical analysis, but its existence in other forms, such as dissolved gas, cannot be proved in this way. It is usually believed that when it is present in sufficient quantity it combines with the iron, making an iron nitride having the formula Fe_4N. In this condition it may be seen as a constituent of the metal in the form of plates (Fig. 7) lying along the cleavage planes of the grains, and with larger quantities is present as a eutectoid of iron and iron nitride at the grain intersections.

Electric arc welds have the same structure as nitrogenized iron, except that the structure is much finer because of the rapid cooling. (Fig. 8.) Gas welds may also contain the plates when the metal has been overheated. Similar plates are also visible in samples of bessemer steel taken just after the blow and before recarburizing. (Fig. 9.) In all three cases the metal has been overheated, and it would seem to be quite possible for nitrogen to combine with iron as iron nitride at these very high temperatures. Of course there is as yet no chemical proof that the plates are iron nitride, as they have not been isolated. It is not worth while to discuss the matter here, except as to



FIGS. 9 AND 10.

Fig. 9. Blown steel from bessemer converter. Short lines at left are iron nitride. Cementite at grain boundaries at right. ×300.

Fig. 10. Electric weld strained. Slip bands frequently stop at iron nitride plates, but in no case do they follow along them, nor do the plates influence the slip bands. ×800.

whether nitrogen is responsible for the brittleness in electric welds made with bare wire. I have tested many welds by bending them and examining them under the microscope, and in no case has it been found that the nitride plates have any effect on the path of rupture. The slip bands in the grains never follow the plates (Fig. 10), but frequently stop at them when the two are at an angle to each other, and the rupture takes place either at defects in the weld, or at the grain boundaries, even where in the latter case no defects are visible, as they also sometimes do in the case of gas welds. This would indicate that as far as tensile stress is concerned nitrogen has no serious effect. In the case of alternating stress and shock tests, the results might be different, but no such tests have been made as far as I know. It seems to me that in view of all the facts the brittleness of welds is due to the presence of oxides, and I believe that in the future we shall be able to make much better welds by providing some effective but simple means for the protection of the melted metal from the air, or for removing from the weld the oxides as they are formed.

[1]While Armco iron does not come within the chemical limits given, the ratio of the strength of a weld made with Armco wire is to its plate strength about the same as that of a nickel steel weld to the plate specified. Also such non-metallic impurities as exist in Armco iron do not seem to impair its welding qualities. They are apparently of a different character.

Water-Power Resources of the World

THE water-power resources of the world and their present development form the subject of Part II of the World Atlas of Commercial Geology, by Herman Stabler, B. E. Jones, O. C. Merrill, N. C. Grower and a group of other co-workers of the United States Geological Survey.

The extreme ultimate development, with the greatest possible conservation of stream flow by storage, of the potential waterpower of the world may reach as high as 10 billion horsepower, but such a figure is purely speculative. The reasonable estimate, when the streams are at ordinary low water stage, is about 440 million horsepower, an amount equal to nearly four times the world's present total used power from all sources. Of this last estimated amount about 190 millions are in Africa, especially in the tropical zone; about 70 millions in Asia, China and India, having respectively 20 and 27 millions; about 62 millions in North America, the United States and Canada having respectively 28 and 20 millions; about 54 millions in South America, of which about half is in Brazil; Europe has about 45 millions, Norway leading with about 5.5 millions; Oceanica has about 17 millions, New Guinea leading with 5 millions. Only about 23 million horsepower—i.e., about 5 per cent of the total reasonable estimate—is now developed, the rank of developments by continents being: North America with about 12,210,000 horsepower, Europe 8,877,000, Asia 1,160,000, South America 424,000, Oceanica 147,000 and Africa 11,000.

Water Power in North America

In outlining the general conditions of the water power in the North American continent nineteen drainage areas are to be considered—namely:

1. *Middle Atlantic Area.* This area includes the basins of all the streams that flow into the Atlantic Ocean between the St. Lawrence River basin on the north and the James River basin on the south. The large demand for power in this most densely populated area of the Western Hemisphere has resulted in the utilization of a great percentage of all the fall sites.

Of the potential 400,000 hp. in New Brunswick, Nova Scotia and Prince Edward Island, about 54,000 hp. is already developed; a 12,000-hp. plant is now being built in Nova Scotia.

The New England water power has been extensively developed. Of the maximum potential 1,605,000 hp. available 1,381,000 is already developed, the principal users, besides public utilities, being pulp, paper, cotton and woolen mills.

Of the maximum potential 2,488,000 hp. in the Middle Atlantic States 1,735,000 is already developed, especially on the Hudson, Mohawk, Delaware, Susquehanna and Potomac rivers. There are also fairly large plants on the Lehigh, Schuylkill and Shenandoah rivers. Most of the developed power is used by public utility plants.

2. *South Atlantic and Eastern Gulf of Mexico Area.* This area includes the basins of all streams that flow into the Atlantic Ocean or the Gulf of Mexico between the Middle Atlantic area and the Mississippi River. Of the minimum 2,000,000 hp. about 1,500,000 is already developed. The greater part of this power is used mainly in cotton mills, although mines, iron and steel mills and miscellaneous manufacturing plants also are great users of water power.

3. *Ohio River Area.* This area includes the entire drainage basin of Ohio River. The potential power of this basin is about 1,500,000 hp., of which only about 400,000 has been developed. A large part of the power developed is for municipal purposes, but practically all the new power development now going on is for industrial use, largely for making cotton goods and aluminum.

4. *St. Lawrence River Area.* This area includes the drainage basin of the Great Lakes and St. Lawrence River to its mouth at Pointe des Monts. The plants near Niagara Falls form the largest water development in the world; their total capacity is 870,000 hp., of which 385,500 is on the United States side. If the total flow of the river were used the Falls would furnish, under favorable conditions, about 6 million horsepower. A plan whereby 60 per cent of the total flow of the river can be diverted for developing power is being considered. The developed power of the St. Lawrence drainage area aggregates more than 2.5 million horsepower, and the potential power is estimated at 10 million horsepower, on the assumption that only 60 per cent of the available flow at Niagara Falls may be diverted for this use. Most of the power developed is applied to municipal uses, but great amounts are also used in electrochemical industries, pulp and paper mills, mining and general industrial plants.

5. *Upper Mississippi River Area.* This area includes the part of the drainage basin of Mississippi River that lies north of the Ohio on the east and the Missouri on the west. The potential power of this area is estimated at about 1 million horsepower, of which 600,000 has already been developed. The power is used mainly for municipal purposes, but mills manufacturing paper, flour, wood products and other articles also use large amounts.

6. *Missouri River Area.* This area includes the entire drainage basin of the Missouri River. Of the total potential 4.4 million horsepower in this area (Montana, Wyoming, Colorado, South Dakota) only about 570,000 is developed. The power developed is utilized principally for mining, smelting, railway and municipal uses.

7. *Lower Mississippi River Area.* This area includes the parts of the Mississippi drainage basin that lie south of the Missouri and of the Ohio. There are only a few water plants in this area, all small.

8. *Western Gulf of Mexico Area.* This area includes the drainage basins of all streams that flow into the Gulf of Mexico between the Mississippi River and Cape Catoche in Yucatan. Only about 150,000 hp. is developed. There is about 50,000 additional potential horsepower on the Necaxa and about 200,000 on the Rio Blanco. Mines and municipal uses offer a market for a large amount of power in this country.

9. *Gulf of California Area.* This area includes the Colorado River drainage basin in the United States and extends to Capes San Lucas and Corrientes in Mexico. The potential power in this basin is estimated to be at least 2 million horsepower, of which less than 200,000 is developed.

10. *Great Basin Area.* This area includes the inland basin between the Rocky Mountains and the Sierra Nevadas. With proper storage the potential power in this area would amount to 500,000 hp. The plants now constructed have a capacity of 250,000 hp.

11. *Upper South Pacific Area.* This area includes the drainage basins of all streams that flow into the Pacific Ocean between the northern boundary of the Klamath River basin and the south end of Lower

SUMMARY OF POTENTIAL AND DEVELOPED WATER POWER IN 1920 IN HORSEPOWER

	Developed	Potential
North America		
Mexico	400,000	6,000,000
United States	9,243,000	28,000,000
Alaska	40,000	2,500,000

(a) Ordinary flow. Ordinary low flow estimated at 2,700,000 hp.
(b) Ordinary low water 900,000. For 9 months, 1,374,000 hp., and for 6 months 2,504,000.
(c) Total power developed, under lea e and availabl · at low flow.
(d) All these estimates except those for the Philippines and New Guinea assume the use of storage.
(e) Installed or under construction, November, 1920.

California, at Cape San Lucas. The total developed power in this area in California is more than 800,000 hp., and at the present rate of increase will soon exceed 1 million. The potential power at low water is about 3 million horsepower, but this amount could probably be doubled by storage. The power is used mainly for irrigation, mining, electrochemical industries and public utilities.

12. *Lower North Pacific Area.* This area includes the drainage basins of all streams that flow into the Pacific Ocean between the Klamath River basin and the Canadian boundary. The potential power is about 11 million horsepower, of which only 750,000 is developed. The power is used mainly by public utilities.

13. *Middle North Pacific Area.* This area includes the drainage basins of all streams that flow into the Pacific Ocean from the U. S. boundary to and including Yakutat Bay, Alaska. The undeveloped power at known sites is between 2 and 3 million horsepower of which only 250,000 is developed. Probably many large sites of potential power are still unknown.

14. *Upper North Pacific Area.* This area includes the drainage basins of all streams that flow into the Pacific Ocean between Yakutat Bay and Cape Prince of Wales. The total developed power in this area is about 65,000 hp., which is used mostly in mining. The undeveloped power is unknown, but may amount to 2.5 million horsepower.

15. *Arctic Ocean Area.* This area includes the northern parts of Alaska, Canada and Greenland. Little is known of the undeveloped power resources of this area, but there seem to be no great concentrations of potential power.

16. *Hudson Bay Area.* This area includes the drainage basins of all streams tributary to Hudson Bay. The potential power is estimated at 5 million horsepower, of which about 225,000 is developed. This power is used for municipal purposes, in pulp and paper mills, in milling and general manufacturing.

17. *North Atlantic Area.* This area includes the drainage basins of all streams that flow into the Atlantic Ocean east of Hudson Bay and north of the St. Lawrence River and Cabot Strait. A 75,000-hp.

plant is said to be feasible on Bay d'Est River in Newfoundland. The only large power plants in this area are in Newfoundland, where 60,000 hp. is developed and used mainly in pulp and paper mills.

18. *Lower South Pacific Area.* This area includes a narrow belt between Cape Corrientes and the eastern boundary of Panama. Although power sites are plentiful and well distributed in most of this area, little power has been developed, because there is little manufacturing and no demand for power except for municipal use in the larger cities.

19. *Caribbean Sea and West Indies Area.* The largest plant in this area is that at Gatun, Panama Canal, of about 13,000 hp. Porto Rico has developed 8,000 hp. of a total potential 25,000 hp. Jamaica has one 1,300-hp. plant. Other small plants are scattered in Honduras, Nicaragua and Cuba.

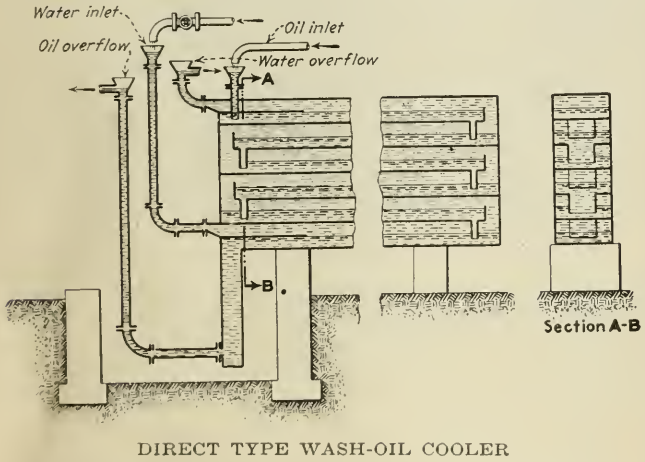
The accompanying tables give the summaries of the potential and developed water power in 1920 by continents and countries.

Direct Type Wash-Oil Cooler for Benzene Plants

By Arthur Kuhn

SEVERAL benzene plants in Germany have adopted what is known as the direct method of wash-oil cooling in which the hot debenzolized creosote oil is brought in direct contact with the cooling water, the effect being that the oil is cooled down almost to the temperature of the entering water.

This process, as well as that of the successful direct gas cooling based on similar principles, emanates from Dr. C. Still, and on account of the imperfection of the small testing apparatus a little initial trouble was experienced just prior to the war. The tests were eventually abandoned, as the cooling effect of a new type of a then inexpensive tubular oil cooler was most satisfactory.



DIRECT TYPE WASH-OIL COOLER

With the present high costs of arranging, cleaning and replacing tubes of the usual coolers, however, less expensive oil-cooling devices are desirable and so the direct cooling has again been taken up and carried through successfully by several coke-oven firms. Though this process is at present confined to European practice, in which heavy tar oil is used in benzene recovery, it will no doubt be of great interest to many coke-oven operators in this country.

Referring to the accompanying illustration, the new type of oil cooler consists of a number of baffle plates or trays combined in a rectangular box, so arranged that there is always a seal pipe dipping into the oil layer at the bottom of every baffle plate in order that the water may not be mixed with the oil.

The creosote oil, which is heavier than water, enters the cooler a little below the top, whereas the lighter cooling water enters near the bottom. In this way the downward-flowing oil is met by a current of water rising from below. With this constant contact of oil and water the oil is cooled to about the temperature of the entering water.

The separation of oil and water is most satisfactory, provided the water is clean and the oil kept in proper operating condition. Naturally, traces of phenols contained in the oil will be diluted and carried along by the water, but this is of little inconvenience, as the water is used for quenching coke.

The process described refers to the cooling of heavy oil only. It cannot be used for cooling straw oil in the same simple way, as no proper counter-current will be assured. The light straw oil would enter at the bottom and travel in an upward direction similar to the water in the former process, whereas the heavier water would be supplied from the top of the cooler. The result, of course, will be that the cooled oil tends to remain at the bottom owing to its increased specific gravity, while the warm water tends to remain at the top, where the cooled oil leaves the apparatus. Undoubtedly there can be no question that these difficulties can be overcome by an apparatus of different design in which the two liquids in question pass each other in one shallow layer.

Pittsburgh, Pa.

The Use of Nozzles in Measuring Pulsating Flow

NOZZLES are one of the most valuable pieces of equipment in measuring the flow of fluids. Their application in the measuring of steady flow is well known and needs no further mention here.

When nozzles and some sort of measuring device for differential pressure are used for pulsating flow, errors result, unless the flow curve is known as a function of time. This fact is easily illustrated by reference to Fig. 1, *A*, which represents flow of fluid plotted against time. In this special case it is assumed that the velocity of flow fluctuates periodically and abruptly between the values of 10 ft. per second and zero. Evidently, the average velocity must equal 5 ft. per second. If, however, the velocity is measured by an instrument such as a nozzle, or a Venturi meter, or a Pitot tube in conjunction with a differential pressure gage, the instrument will not measure the average velocity directly, but its readings will fluctuate between 10^2 and 0^2—i.e., the readings will fluctuate between 100 and 0. If now the gage be throttled down so that it can be read, then it will show the average between 100 and 0 or 50. However, the square root of 50 does not equal 5, but is a little more than 7, and the conclusion is that the instrument will show 7 ft. per second instead of the actual average velocity of 5 ft. per second. This in itself would do no harm if we knew beforehand how much the excess reading is, but, as before stated, to that end we must know the flow curve. Let the flow curve be as in Fig. 1, *B*, which again represents velocity of flow plotted against time, and let the velocity fluctuate now only between 6 ft. per second and 4 ft. per second, then the

readings of the instrument will fluctuate between 36 and 16, these being the squares of 6 and 4. The average between 36 and 16 equals 26 and the square root of 26 is but little more than 5, from which it can readily be seen that the error becomes quite small if the violence of the fluctuations of flow can be decreased or damped. Several means can be employed for accomplishing this result.

In the testing or in the regular supervision of the air delivery of reciprocating compressors it is quite possible to install a large tank between the compressor and the delivery line. This tank may well act as an aftercooler for removing the moisture from the air. If this

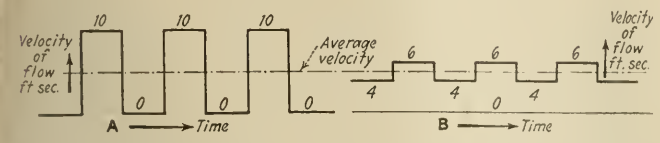


FIG. 1. FLOW CURVES WITH VELOCITY FLUCTUATING PERIODICALLY: *A*, OVER A WIDE RANGE; *B*, OVER A NARROW RANGE

tank be about three or four times the volume of the high-pressure cylinder, the flow fluctuations are greatly reduced, and if in addition a throttling flange be applied at the end of the tank—i.e., at the place where the tank joins the delivery pipe—then the flow in the delivery pipe will be made quite even and a nozzle or a similar instrument can be used with great accuracy. The larger the tank and the smaller the throttling flange the more uniform is the flow. The flange need not be so small as to produce any noticeable pressure drop.

The same method can also be used in the application of steam meters to measure the flow of steam for reciprocating engines. Every engine should be equipped with a large receiver separator, and can in addition be equipped with a throttle flange at the place where the steam main joins the receiver separator. The flow is made even enough to apply a steam meter and to accept its readings without any correction.

It has also been suggested that the flow in lines carrying variable velocity fluids can be made even for a distance by placing a fan in the line at either side of the nozzle or of the measuring instrument, the theory being that the fans have inertia and resist pulsating flow, thereby reducing the violence of the pulsations.

In the testing of air compressors and blowing engines, or of Roots blowers, the following methods for the ap-

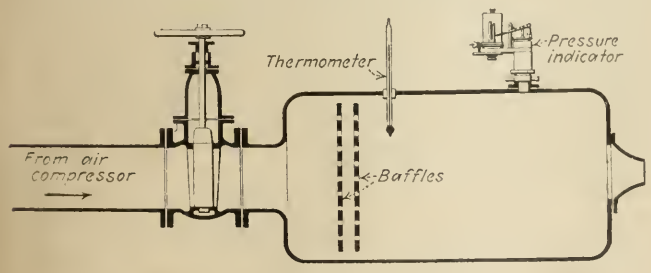

FIG. 2. USE OF NOZZLE IN DISCHARGE LINE OF COMPRESSOR

plication of nozzles have been found quite successful. As shown in Fig. 2, a valve may be placed in the discharge line from the air compressor or blowing engine, and a tank with the nozzle may be placed at the end of the line. The valve serves the purpose of varying the pressure against which the compressor discharges, and at the same time reduces the fluctuations of flow in the tank. The fluctuations proper can be measured by indicator which is mounted on the tank, and the drum of the gage is pulled as evenly as possible by hand. The indicator gives at once the average pressure in the tank and the fluctuations of pressure. The diameter of the nozzle and the pressure of the air in the tank, together with its temperature, immediately give the quantity of air flowing. Any corrections for variations in velocity can be made as indicated in Fig. 1. The baffles are necessary for eliminating the effects of velocity of approach upon the nozzle and should consist of perforated plates or strong wire mesh.

For the ordinary run of shop compressors, it is usually preferable to test the compressor while it is in operation. This can be done by using nozzles on the inlet side, provided, of course, that the piston rod packings are tight. In this case it is quite easy to obtain uniform flow by attaching to the compressor inlet a sheet-iron box which carries the nozzle or nozzles, and which in addition is equipped with a rubber diaphragm as shown

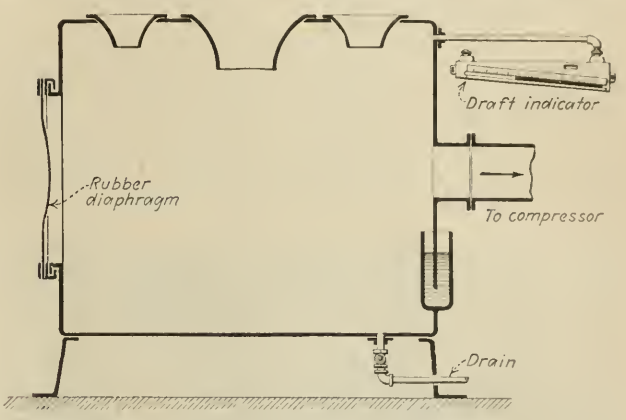

FIG. 3. USE OF NOZZLE ON INLET SIDE OF COMPRESSOR

in Fig. 3. The volume of the box acts as an equalizer and the rubber diaphragm which flops in and out helps materially to maintain an almost constant flow through the nozzles. A box of this sort is a very valuable adjunct to mechanical laboratories and especially in shops where air compressors are built or used, because it allows testing of the actual air compressor delivery with very little trouble. To this end, it is advisable to have several nozzles in the box and to plug up those which are not in use. It is very desirable to have a safety valve on the box to protect the rubber diaphragm from injury in case someone should close more nozzles than is good for the rubber.

Such a safety valve is indicated on the right hand side of the box in the shape of a U-tube full of water. The section of the U-tube must be large enough to prevent the formation of such a vacuum in the box as might break the rubber diaphragm. The pressure drop of the nozzles can be kept quite small, and can be measured by means of an inclined gage such as a draft gage. The pressure drop through the nozzles amounts to much less than the variations in barometric pressure and no fear need exist that the measuring box will in any way interfere with the air delivery of the compressor.

Nozzles have not been used for testing to the extent which they deserve, probably for the reason that it is troublesome and expensive, first, to lay out nozzles, and then to machine them. These obstacles, however, were removed some time ago by the Bacharach Industrial Instrument Co., of Pittsburgh, which has standard nozzles

for almost all purposes of testing. It may therefore be hoped that nozzles will be used more in the future for the testing of reciprocating machinery. It may also be stated that the discharge from positive blowers, such as the Roots or Connersville blowers, is likewise pulsating and needs some means to reduce the fluctuations.

Occasionally, it is practically impossible to damp the vibrations on account of the size of the equipment—for instance at the air inlet of blast furnace blowing engines. In that case the flow velocity curve can be determined occasionally by placing in the nozzle a very light flapper and by recording its motion on an indicator. In the use of such an instrument it is frequently found that, during very short intervals, the air actually blows back.

Welding Curved Pipe Coils of a Glucose Tank

As the result of an unforeseen circumstance a thermit pipe-welding job of unusual nature was recently performed on a helical 2½-in. standard pipe coil for the American Chicle Co., Long Island City, N. Y.

The coil in question was to be used to convey steam under pressure for heating a glucose tank and was first constructed in one piece measuring about 17 ft. in outside diameter and 14 in. from pipe center to pipe center of adjacent pipe turns. Because of the large size of the coil, however, it was impossible to transport the coil to the place where it was to be installed, so it

THERMIT WELDED CURVED PIPE COIL

was necessary to cut the coil with an oxyacetylene torch into two semi-circular segments by making nine cuts and later thermit welding these cuts together.

As the cutting torch had left ragged edges, the pipe ends first had to be backsawed. The surfaces to be welded were next faced smooth with a pipe-facing machine and the usual pipe-welding operations then followed. Immediately after each weld was made the section having one end just welded and the other end about to be welded was bent around to a shorter radius and into a proper position for the next weld, the red hot temperature of the weld just made enabling this bending to be made.

The results of the welding were entirely satisfactory in every way, continuous joints being obtained with no trace of leakage whatsoever during a preliminary test of the welded coils under 40-lb. steam pressure and later in service under a 5-lb. pressure intermittently for about 2 months up to the time of writing.

The work was undertaken for the American Chicle Co. by the Carrier Engineering Corp., Newark, N. J.

Synopsis of Recent Chemical & Metallurgical Literature

The Formation of Pearlite in Steel.—In a paper on this subject read before the Cleveland (England) Institution of Engineers, and abstracted in *Iron and Coal Trade Review*, Dec. 9, 1921, J. H. Whiteley showed that pearlite can grow directly from a solid solution of carbide of iron in gamma iron without the formation of any intermediate stages, and that the so-called transition stages, troostite and sorbite, should be regarded as alternative or side products of the transition. He gave evidences of "lag," showing that a certain degree of supersaturation is required before pearlite will form, and that growth never starts within the area, but at the boundary, apparently through inoculation by the adjacent ferrite or cementite, as the case may be. The average coarseness of the pearlite was not found to depend either upon the lenght of heating or maximum temperature, but simply upon the rate of cooling through Ar_1. This was explained as due to the greater opportunity allowed, in slow cooling, for solution and diffusion of the carbide to occur whereby the spacings are widened. The maximum width of ferrite laminæ yet seen is slowly cooled hypo-eutectoid steel is $\frac{1}{22,000}$ in. With a given rate of cooling, the presence of manganese and silicon in steel increases the fineness of the pearlite, and pearlite formed in the presence of free cementite is much coarser than that formed either in eutectoid or hypo-eutectoid steels. Apparently this effect is due to the manner of inoculation.

Standard and Tentative Methods of Sampling and Testing Highway Materials.*—This publication gives in full the methods recommended by the second conference of state highway testing engineers and chemists as adopted at their meeting in Washington early in 1920. Many of the methods are those of the A.S.T.M. Most of the others are those which have previously been recommended by the bulletins of the U. S. Department of Agriculture Bureau of Public Roads. The bulletin includes more than fifty methods of testing or analysis for both non-bituminous and bituminous road materials, including stone, sand, cement, brick, bituminous products, etc. Full recommendations are included of standard methods for sampling each of the important materials.

Production of Iron by Direct Electrothermic Reduction of the Ore. (Levoz Process).—Marcel Guedras in *Technique moderne*, vol. 13, p. 264, (1921) describes the Levoz process. Essentially it consists in the formation of ferro-alloys in a reaction mass, which later purify iron oxide. The process comprises three distinct stages as follows:

First, oxides of iron, manganese and other easily reducible metals are reduced by carbon. No details of the furnaces are given, but they are so designed that the aluminum silicates of the ore react with the iron oxides, in the presence of C, to give ferrosilicon and alumina, which later dissolves in the cryolite flux which is added to the charge.

Second, the Al_2O_3 dissolved in the flux prevents the volatilization of any reduced aluminum metal and also the oxidation of the iron in the crucible. The iron absorbs the aluminum reduced by the carbon in the bath, forming ferro-aluminum and eliminating at the same time any iron carbide which has formed. With the ferrosilicon formed in the first stage the Al forms an Fe:Si:Al alloy, which is a powerful reducer and which gives rise to strongly exothermic reactions. At the end of the second stage the mass consists of a layer of slag over this complex ferro-alloy dissolved in iron and manganese.

Third, the molten mass flows into an electric furnace containing a charge of the ore to be reduced. The strongly reducing, complex ferro-alloy reacts with the oxides in the

*Bulletin 949, Department of Agriculture.

ore with great evolution of heat, so that the greater part of the heat absorbed in the two stages above is recovered and the current consumption in the third stage is very small. The slag, consisting of double silicates and of cryolite, has a very low melting point and is easily separated from the metal. The silicon, manganese, aluminum and calcium in the complex alloy first produced carry the metallic oxides and sulphides completely from the ore into the slag with formation of very fluid silicates. There remains a pure iron which may be either drawn off as such or converted into steel. The cryolite reacts with the lime of the charge to form CaF_2 and $Al_2O_6Na_6$; but this does not interfere with the main reactions.

The first step of the process is carried out in a reduction furnace with an inclined hearth, emptying into a crucible for the second stage and an electric furnace for the third, the molten metal flowing from one to the next by gravity.

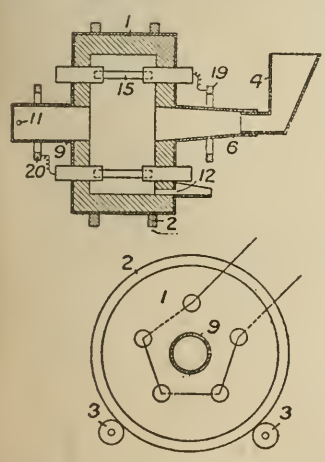
Advantages of the process are said to be: Any kind of ore can be treated. The cost of the plant is much less than that of a blast furnace, and the product obtained is pure iron or steel. There is an important saving in fuel. Reducing gases having a high caloric value are utilized. By suitable combination of furnaces, any grade of iron or steel can be obtained. The consumption of electric energy is reduced to a minumum owing to the strongly exothermic reactions of the aluminum alloys in the third stage. Finally, cost of labor is low.

Recent Chemical & Metallurgical Patents

British Patents

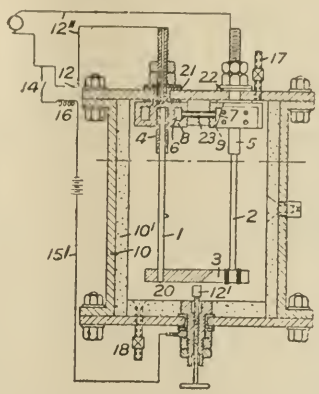
For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Electric Furnace for Continuous Conversion of Zinc Dust Into Molten Zinc. An electric furnace for the continuous conversion of zinc dust into molten zinc comprises a cylindrical casing 1 surrounded by rings 2 which run on rotating rollers 3 whereby the furnace is given a rotary motion. A coned inlet tube 6 is fitted axially in one end of the furnace and zinc dust is fed into this tube from a hopper 4. A tube 9 is similarly fitted axially at the other end of the furnace and is provided with a number of adjustable openings 11 through which the residue escapes and by which the working of the furnace may be controlled. The molten zinc may be tapped off through an opening 12 in the furnace casing. The resistance members 15 are arranged concentrically round the axis of the furnace and are coupled up, as shown, and fed with current from contact rings 19, 20. (Br. Pat. 168,018. C. E. Cornelius, Stockholm. Oct. 12, 1921.)



Purifying Gases. A process for the removal of sulphur compounds from coal or like gas consists in washing the gas with both a volatile oil such as benzene and a stripping oil such as creosote of which not less than 500 gal. are used per million cubic feet of gas. These oils may be mixed or used separately. Paraffin oil may be used instead of creosote, particularly if finely divided alumina or charcoal be suspended in it, and the stripping oil free from benzene may be introduced into the washer and benzene vapor added to the gas entering the washer. Thiophene may be removed by treatment with sulphuric acid and the benzene and creosote used again in a cyclic process. (Br. Pat. 168,482. South Metropolitan Gas Co., E. V. Evans, H. Hollings and H. Stainer, London. Oct. 26, 1921.)

Refining Tungsten.—A process for the manufacture of ductile rods from high-fusing metals such as tungsten, molybdenum, etc., or alloys of the same consists in heating rods made of the said substances hung vertically in a vessel containing neutral or reducing gas at high pressure by the passage of an electric current or by an electric furnace, bringing them to a nearly molten state and then using the elongation of the rods to stop automatically the heating current supplied to the rods or furnace. Two rods of tungsten 1 and 2 are placed vertically in a vessel 10 lined with refractory material 10′ having openings 17 and 18 provided with cocks for the inlet and outlet of the inert gas, the lower ends 20 of the rods 1, 2 being connected by a horizontal tungsten rod 3. The upper ends of the rods fit into two electrodes 4, 5 which are fixed to two other electrodes 8, 9 having water jackets 6, 7 joined by a pipe 23 of insulating material, these electrodes 8, 9 being insulated from one another and the vessel 10 by insulating-pieces 21, 22. The heating current is supplied to these electrodes 8, 9 through lines 12″ of low resistance upon closing a switch 12, and the elongation of the rods 1 and 2 causes contact between the rod 3 and an adjustable insulated electrode 12′ which allows the current to pass through a local circuit comprising a low-resistance line 15″, a switch 14 normally closed, and a trip coil 16 which then opens the main switch 12. When the rods are heated by an electric furnace, the elongation of the rods make contact as before to close a local circuit which may operate means to cut off the main heating current. If the material of the rods contains impurities, the rods may be heated initially under a reduced pressure to eliminate the impurities by vaporization and later the high pressure applied. (Br. Pat. 168,697. E. Aoyagi, Kyoto, Japan. Oct. 26, 1921.)



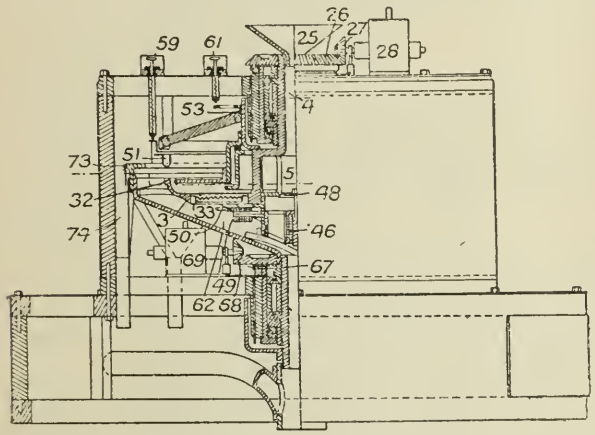
Froth-Flotation Process for the Concentration of Oxidized Ores. In a froth-flotation process for the concentration of oxidized ores such as cassiterite, or oxidized ores of tungsten, lead, zinc, or copper, carbon dioxide or a gas containing it is introduced into the pulp as a gangue-modifying agent. A mineral-frothing agent may be used consisting of or containing a fatty acid or a fatty-acid compound such as soap. The carbon dioxide or gas containing it may constitute both the gangue-modifying agent and the flotation agent. (Br. Pat. 168,098. L. A. Wood and Minerals Separation, Ltd., London, Oct. 12, 1921.)

Glycerine.—In a process for treating waste liquors of alcoholic fermentation for the extraction of glycerine, the liquors are neutralized with lime or chalk, filtered and boiled with ferric chloride, preferably under pressure, until the liquor no longer reacts with Fehling's solution. The iron is precipitated by lime, and then the lime by carbonic acid or sodium carbonate. The resulting liquor is filtered, concentrated and distilled. In a modification, ferric sulphate is used instead of ferric chloride, the iron being then precipitated by baryta instead of lime. (Br. Pat. 168,833 Barbet et Fils et Cie., Paris. Nov. 2, 1921.)

Purifying Tannins.—Tannins, preferably those extracted from the raw materials with the aid of acids, are purified by conversion, by the action of bases or basic compounds, into insoluble or difficultly soluble salts which are freed from impurities by washing with water or organic solvents and then decomposed by acids or in some cases by salts; the tannin solution is finally evaporated. As basic compounds may be used magnesium oxide, hydroxide or carbonate, or the corresponding barium, strontium or calcium compounds and two or more bases may be used successively or conjointly. For the decomposition of the tannin compounds, acids or salts which will give insoluble compounds

with the base or bases employed are preferably used. The crude tannins may be previously treated with reducing agents, such as sulphurous acid, hydrosulphurous acid or "other acids of sulphur," but preferably with volatile reducing acids. (Br. Pat. 169,722; not yet accepted. Byk-Guldenwerke Chemische Fabrik Akt. Ges., Berlin. Nov. 16, 1921.)

Electrostatic Separators. In the electrostatic separation of finely divided material such as metal-bearing ores, the material is dried by heating elements while being spread centrifugally in a rotating pan, from which it is discharged into an electrostatic field wherein the susceptible particles are sustained against gravity so as to become separated from the less susceptible particles, which fall to a different



point of discharge. Apparatus for effecting such a separation comprises a pan 3 the rim 32 of which forms one electrode, a second annular electrode 51 being situated above the rim of the pan and the whole being rotated along with the hollow shaft 4 by a motor 28 through gearing 26, 27. The material to be separated passes down the hollow shaft 4 from the hopper 25 into the pan 3 through a chamber 5 and is dried by heating elements 33 in the bottom of the pan. The particles are cast centrifugally against the rim electrode 32 and the susceptible particles are carried upwards in their centrifugal travel through the electrostatic field over the edge of a dividing-ring 73 and into hoppers 74. The less susceptible particles falling on the inside of the ring 73 into the hopper 62, which may be given an opposite rotation through gearing 67, 68, pass down the shaft 4 to waste or, if a further separation is desired, to the next pan of a series. In the hopper 69, a transformer 49 may be provided to supply a spark at gaps 50 for preventing the dispersion of dust, and a bypass valve 48 operated by a solenoid 46 may be provided in the shaft for cutting-out steps in the separation where a series of separators are used. Low-tension current is conducted to the heating elements 33, transformer 49 and solenoid 46 through a brush 61 and ring 53, and the high-tension supply to the annular electrode 51 is through a brush 59. (Br. Pat. 168,479. G. R. Brown, Bondi, near Sydney, New South Wales. Oct. 19, 1921.)

Hardening Oils.—Unsaturated oils are catalytically hydrogenated by treatment with a material which is capable both of giving off hydrogen and of acting as a catalyst. This material is prepared by melting together certain metals, such as iron, manganese, ferromanganese, copper, tin, zinc, lead, aluminum, antimony, nickel, cobalt and bismuth, to form an alloy which is stated to evolve hydrogen when added to the oil alone or to oil containing water. The particular alloy mentioned as an example is composed of ferromanganese, aluminum, antimony, nickel and lead in stated proportions. (Br. Pat. 169,147; not yet accepted. W. P. Heskett, Waiotahi Creek, Thames, New Zealand. Nov. 2, 1921.)

Synthetic Resins.—Phenol or its homologs when condensed with acetaldehyde or its polymers produces a resin which is soluble and does not harden on heating. Formaldehyde or its polymers may be added at any stage of the process to render the product less soluble or insoluble or to make it harden. Acids, bases and salts may be used as accelerators, the following being mentioned as suitable: sulphuric acid ammonia, caustic alkali, oxalic acid and phenyl hydrazine hydrochloride. (Br. Pat. 169,347. H. V. Potter and W. F. Fleet, Birmingham, and Dainard Lacquer Co., Ltd., Westminster. Nov. 9, 1921.)

Treating Hides and Skins.—Comprises a process for depilating hides and skins in which extrinsic bacteriological or saprophytic enzymes are inactivated while the action of thrombase (thrombin) which is stated to be found in the skins, especially at the roots of the hairs, is encouraged or activated. The extrinsic enzyme system, to which the term "saproprotease" is applied, is inactivated by the use of end products of proteoclastic enzyme action such as ammonia or compounds producing ammonia, amino acids, skatol and indol. The intrinsic enzyme, thrombase, is activated by the addition of easily dissociated calcium salts or compounds such as the lactate or polysulphides thereof. The activator and inactivator are mixed together in the form of a solution, the inactivator preferably comprising a 1 per cent solution of ammonium hydrate. The action of the intrinsic enzyme may be assisted by the addition of trypsin or other proteolytic enzymes which will work in an alkaline medium. The depilation is stated to be effected without destroying the epidermis, so that comparatively large sections thereof with the hair attached can be removed. Subsequent bating is unnecessary. In preparing dressing leathers, the solutions are heated, while for sole leathers cold liquids are employed, these allowing imhibition or plumping to take place to a greater extent. The process may be employed in the treatment of diseases, but no claim is made for this application of the invention. The provisional specification describes also the use, to assist the depilatory action, of pepsase and in certain circumstances of the saprophytic extrinsic enzyme which is therein termed "saprophase." (Br. Pat. 169,730. H. C. Ross and Walker & Sons, Ltd., Bolton. Nov. 23, 1921.)

Methylamine.—Gases or vapors are minutely subdivided in passing through a series of porous diaphragms and layers of liquid thereon in order to effect their maximum contact with liquids. The process may be applied to the treatment of gases from petroleum stills, coke ovens and gas producers, with liquids which may contain substances in suspension. The gases and vapors from the still 1 pass through the compressor 3 to the bottom of one of a series of diffusers shown in section in Fig. 2, comprising

FIG.2.

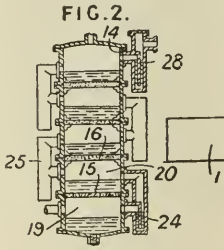


FIG.1.

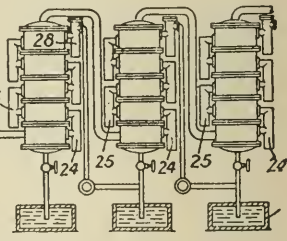

a shell 14 containing gas-porous diaphragms 15, 16 . . . which form compartments 19, 20 . . . connected in series by ducts 24, 25 . . . having liquid seals. The gases penetrate upward through the successive diaphragms and the liquid borne thereon, which enters at the inlet 28 and to the extent limited by the height of the duct inlets flows in counter current. The gases are led to the bottom of the next diffuser, from which liquid may be pumped to the previous one, or the liquid may be discharged from each diffuser into separate tanks. (Br. Pat. 169,605. Canadian American Finance & Trading Co., Ltd., Victoria, B. C., Canada. Nov. 16, 1921.)

Wood and Like Cellulose Pulp and Fibers.—In the preparation of light-colored strong fibrous material for the paper trade from wood or other substance containing cellulose, in logs or billets, the material is saturated, softened or boiled with water in vacuum or under mechanically produced water, air or steam pressure. Either a high temperature

of 105 to 120 deg. C., or a low temperature of about 80 deg. C. and a high pressure of from 5 to 10 atmospheres or a low pressure of about 350 mm. of mercury may be employed. Neutral, acid or alkali reagents may be added to the water. A flowing movement of the liquid used is maintained in the direction parallel to the direction of the fibers of the wood. When treating under vacuum, an air pump is used during the whole operation, lasting 6 to 8 hours, the drop in temperature being made up by indirect heating. (Br. Pat. 169,802. L. Enge, Niederschreiberau, Silesia, Nov. 23, 1921.)

Book Reviews

THE MANHOOD OF HUMANITY. THE SCIENCE AND ART OF HUMAN ENGINEERING. By *Alfred Korzybski*. Pp. 264. New York: E. P. Dutton & Co. Price $3.

Here is a book which we believe would have delighted the heart of the late William James. It is easy to read, and no one need fear that he will go to sleep over it. It isn't dull, or involved, or even subtle. If a reader tries to be subtle in reading he will miss its bigness.

Early in the work the question is asked, What is man? The answer given is full of illumination. We know life, the author says, in three phases, as plant, as animal, and as man. The plant is a chemical phenomenon. The animal is also a chemical phenomenon, but it has another dimension. It controls, or "binds," as Count Korzybski says, space. The author means space on or about the earth, space of three linear dimensions; the space in the fields, in the woods, among houses and along the road; space without any cosmic complexities. The animal goes or walks or flies whither it will, which the plant does not do. If your metaphysical conscience urges you to protest against the postulate of will in animals, then substitute desire or any other word that will indicate the quality that we know does exist. The plant is a chemical phenomenon. The animal is a chemical phenomenon, but it also binds space. Man has both these attributes; he is a chemical phenomenon, he binds space, but to him is added a third dimension which makes him a different being from animals. He has control over and "binds," as the author says, time. Man binds time. No plant or animal does this. By time we mean that which is ticked off by the clock, and is measured by seconds and minutes and hours and years and centuries. Please do not try to get off the earth in regard to time or space, even in imagination, when you read this book.

The difference between an animal and man as timebinder is immense. The beaver, for instance, builds his dam according to his instinct and in the same way that beaver dams have been built for hundreds of thousands of years. Each generation builds for itself, and does not learn from the past. When man builds a house he uses not only his instinct for protection against the weather; he avails himself also of the experience, the work and the inventions of the dead, adding to this his own inventions, and thus makes a house different from that of former generations. He has the capacity to improve on earlier houses. Plumbing, elevators, electric annunciators and the like are incidents of invention added originally by living men to the inventions of men who were dead.

Let us cite a couple of examples in which the time-binding faculties of man have been actively employed, and observe what progress follows. In the past 125 years great advances have been made in the mechanic arts. They have been no less than amazing. The reason for this is that through patent records and by the increased means of communication which inventions have brought about man has been informed of the experiences of previous generations, has learned the particulars of the work of the dead, and has added his own inventions to these. A similar curve of progress has taken place in the natural sciences during the past 60 or 75 years. Discovery leads to discovery. In no other walk of life is there so complete a historical perspective available as in the natural sciences and in the mechanic arts. This progress has been due to the fact that when he so wills, man—and man alone—can make of the past, the present and the future one continuous *now*.

Consider the progress in other respects and we find no such curves. The reason is that we have tried to organize continuance by tradition without the aid of experience on the one hand, or we have become so offended by tradition that we have vainly tried to organize methods of human behavior out of our own puny, ignorant, narrow, unenlightened imagination. We have blundered about as we do, for instance, in matters of government, like little children with no one to guide them.

Let's say that man as a time-binding creature is old as we count a lifetime, but young on earth. He has grown some, but how much has he grown as an intelligent being, say since the days of Babylon? The sandy desert which is Babylon today is scarcely an improvement over the city of hanging gardens that was. We get ahead in one respect and go back in another. The lusty artisan of Renaissance days, singing as he worked, making things of a quality of beauty that we cannot reach, surely had a more abundant life than the factory hand of today, whether he could read and write or not. He had the joy of artistic creation, which is a delectable state, unknown to most of us.

We have, by means of engineering, been diligent in conserving materials to the best uses, and in avoiding wastes of them, but we have been neglectful in conserving humanity. We look after man's health somewhat as we look after the health of animals, but we have not looked after man as a time-binder. And he is that. Not one of us can loosen himself from this line of time. We can't get rid of our participation in it. Then let's follow the author again and note again what we can do in this respect.

Time proceeds in arithmetical progression as it is ticked off by the clock, or is measured by the years. Man as a time-binder can progress according to a different ratio. The first of a series of generations, for instance, has its experiences, meets its difficulties and solves its problems by invention. The second has the advantage of the experience and work of the first, and to it adds its own experience. The third adds to this, and so on, so that the line of progress of time-binding man may be geometric rather than arithmetical. The lofty heights of understanding, of intelligence, of welfare in the arts of living, to which humanity may attain, are stupendous. It is a problem, as Mr. Korzybski puts it, of engineering. He has worked out a mathematical formula which is the first step in showing the available rate of progress, and this is a practical rule. As soon as we begin to compute human progress by means of mathematics we shall begin to know our shortcomings. We need to integrate our work in relation to the general welfare. The book is full of hints in this direction.

Here's another point of attack. No man ever "makes" a fortune. He collects it. Thousands and thousands of dead have contributed to it. The wealth of the world is in the main a great treasury left by the dead. Our business is to carry it on. Anyone who destroys such results by misuse of it is not living the life of a human being; he is living the life of a ghoul. He is preying upon the dead, and neither legalistic title nor documentary ownership alters the fact. Everyone is a time-binder. Everyone is passing on the work of the past to the future. What are we doing with it?

We have claimed that man is a highly developed animal. He has many of the organs and the space-binding qualities of an animal, but he is not any more an animal than a cube is a plane because it has planes as parts of its structure. Then we have said that man is part animal and part something supernatural. That means that he is part something that we can understand and part something that we cannot understand. It is dodging the question and does not lead to progress. It is a lazy thought and irreverent to whatever Greater Intelligence there may be beyond our senses. Our business in life is living, and we should make the best of it. ELLWOOD HENDRICK.

Proposed Merger of Fertilizer Companies Expected to Materialize Next Spring

Consolidation plans are under way among about thirty-five independent companies manufacturing commercial fertilizers for a merger of interests. A meeting will be held early in January, it is stated, to perfect details of the proposal, and it is expected that definite plans will be developed to bring about the change in the spring. The move is being made on the basis of business economy, with idea of concentrating operations at certain plants, operating under full capacity, and shutting down other works until conditions in the industry warrant resumption. Among the companies interested in the movement are the Davison Chemical Co., Piedmont-Mt. Airy Guano Co. and G. Ober & Sons Co., all of which operate plants in the Baltimore, Md., district.

Registration of Professional Engineers in West Virginia

Pursuant to Chapter 106, acts of the Legislature of 1921, it will be unlawful to use the title of "Registered Professional Engineer" in West Virginia unless actually registered with the State Board of Registration for Engineers, Charleston, W. Va. The official roster will include civil, structural, mechanical, electrical, mining, metallurgical and chemical engineers.

Registration is not compulsory except for those desiring to use the title. The initial fee is $20 and the yearly renewal fee $10. Application blanks may be obtained from George E. Taylor, Secretary, 504 Coyle & Richardson Building, Charleston, W. Va.

Fertilizer Manufacturers Want Pyrites and Crude Oil Kept on Free List

Formal requests have been made of the Senate Finance Committee by the National Fertilizer Association that pyrites and crude oil be left on the free list. The committee's attention has been called particularly to the conclusion of the United States Tariff Commission that the serious competition which domestic pyrites producers face comes from American sulphur rather than from imported pyrites.

In this connection it is pointed out to the committee that prior to the war approximately a million tons of foreign pyrites was imported annually for use in sulphuric acid manufacture. During the war foreign pyrites was supplanted largely by domestic sulphur as the raw material for sulphuric acid. As a result of the war there has been a large increase in sulphur production. The price of sulphur has declined to the point where foreign pyrites no longer can compete with it, it was argued, except at points highly favored in the matter of transportation, such as Atlantic ports. It is claimed that even under the stimulus of war prices the production of domestic pyrites remains small. A tariff on pyrites would have the effect of prohibiting further importations, but it is contended that sulphur and not domestic pyrites would be substituted unless sulphur producers, because of the tariff, greatly advanced their prices. With sulphur at its present price, it is pointed out, the consumption of foreign pyrites has fallen to less than a quarter of the pre-war tonnage.

The point is also made that a tariff on pyrites would be a standing invitation and a constant temptation to the sulphur producers to add the amount of the duty to the price of their products. That the domestic sulphur industry needs no protection is apparent, it is pointed out, by the fact that it has displaced the Sicilian product in the important Scandinavian markets and is being sold extensively in England, France, Germany and Africa.

With regard to fuel oil, C. H. MacDowell, president of the National Fertilizer Association, in a statement submitted to the committee, among other things says:

> The National Fertilizer Association regards with apprehension the announced purpose of representatives of certain oil-producing companies to urge a tariff duty on imports of crude oil. We had believed that question was settled definitely some months ago when the House of Representatives, in response to the overwhelming sentiment of the country, as affirmed in a letter from the President, rejected the recommendation of the Ways and Means Committee for a duty and voted to retain oil on the free list. To learn now that efforts for a duty will be renewed and to hear that such efforts are receiving some support in the Finance Committee is very disquieting.
>
> The fertilizer industry, struggling out of a period of unparalleled depression, is in no position to bear the burden of a tariff on oil. The losses of the past season, due to a decline of about 50 per cent in the use of fertilizer, were not confined to fertilizer manufacturers. There followed reduced yields of field crops, causing tremendous losses to farmers and business generally. C. R. Capps, vice-president of the Seaboard Air Line Railway, testifield at the hearing before the Interstate Commerce Commission Dec. 16 that the loss of fertilizer tonnage to the railroads of the South this year amounted to more than 2,000,000 tons. To that primary loss must be added the potential crop tonnage which such a quantity of fertilizer develops.

Many of the large fertilizer plants on the Atlantic seaboard use Mexican crude for fuel. In addition practically all the power used in the mining of phosphate rock is produced from plants using Mexican crude oil for fuel. It is contended that a tariff on crude oil would increase greatly the cost of fertilizer without bringing any corresponding benefits to domestic oil producers.

Shipment of Steel by Barges on Inland Waterways System

Considerable interest is being taken by communities along the Ohio and Mississippi rivers in the possibility of using the inland waterways system of the country for handling steel trade in quantities. This has been greatly quickened by the success of the Jones & Laughlin Steel Co., of Pittsburgh, which has already sent two large fleets of barges carrying approximately 400 carloads of steel products south on the Ohio and Mississippi from its works in the Pittsburgh district, and is preparing to continue the service as a regular factor in its distribution system.

The first tow, carrying about 100 freight carloads, left the Pittsburgh harbor the last week in October, and distributed its cargo to Huntington, Louisville, Evansville and St. Louis. The second tow, three times as large as the first, carrying 300 freight carloads of steel products, started down the river the first of December, proceeding as far as Memphis, unloading parts of its cargo at several intermediate points.

Not only is the steel company planning an increase in use of the inland waterways system, but has advised some of its customers in Memphis and other points that it is looking into the possibility of the use of seagoing steel barges for delivery of steel products to such points and, in time, to the ports on the Pacific Coast by way of the Panama Canal.

F. E. Hackett, general manager of sales of the Jones & Laughlin Co., is responsible for the inauguration of this new service.

More Plants in Many Lines of Industry Increasing Operations

Paper—The French Paper Co., Niles, Mich., is operating its local mills at full capacity. A number of improvements are being made at the plant.

The American Writing Paper Co., Manchester, Conn., has resumed production at its local Oakland mill, following a shutdown for about a year past. All former operatives have been engaged and full-time production schedule has been adopted.

The Consolidated Paper Co., Milwaukee, Wis., has resumed full-time operations at its Wisconsin Rapids and Biron mills. The plants have been running on part time for some months past.

Ceramics — The H. E. Buck Manufacturing Co., Lake Charles, La., will take possession of its local plant, effective Jan. 1, heretofore operated under lease by other interests. It is proposed to resume full operations at once for the manufacture of building brick.

Potteries devoted to the manufacture of dinnerware in the eastern Ohio district are now operating in excess of 80 per cent capacity. Production is greater than at any time during the past year. Electrical porcelain potteries are producing under a full-time schedule at capacity output.

Glass — The Sneath Glass Co., Hartford City, Ind., is maintaining active production at its plant, and has distributed a bonus of $10,000 among its employees.

Oil—The Standard Oil Co. has resumed operations at its Bayway refinery, Elizabeth, N. J., after a curtailment for about 8 months past. Employment will be given to about 500 operatives. Effective Jan. 1, the 4,000 employees at the Bayonne refinery went on full time, as compared with 5 and 5½ days previously.

Rubber—The General Tire & Rubber Co. is increasing production at its plant at Akron, Ohio. Plans are being considered for doubling the present capacity during 1922.

Effective Jan. 1, the Mason Tire & Rubber Co., Kent, Ohio, has increased production from 2,300 casings a day to 4,500 casings. The plant is working on three shifts and giving employment to about 1,000 persons. This number will be increased by approximately 700 additional operatives at an early date.

Copper—The Utah Copper Co., Bingham, near Salt Lake City, Utah, is planning for the resumption of operations at its plant at an early date, probably in February, giving employment to more than 2,500 men.

Metals—The silver and lead producers in Utah and Idaho are increasing operations. During the last week in December three additional silver-lead furnaces were blown in, and others will start up at an early date.

Iron and Steel—The Lackawanna Steel Co., Buffalo, N. Y., is maintaining a production about 50 per cent of normal, and is said to be planning for an early increase.

The Bethlehem Steel Co. has continued the operation of its coke ovens and blast furnaces at the Steelton, Pa., works throughout the holiday period. Departments closed down during this time to permit repairs and improvements to machinery will resume production at once.

The Colorado Fuel & Iron Co. has arranged for the immediate resumption of operations at its steel mills at Pueblo, Col., on a 50 per cent basis, giving employment to about 2,000 men. The company recently reopened its iron mines on a 40 per cent production schedule.

The Carnegie Steel Co. is operating two blast furnaces at its Mingo Junction plant, near Steubenville, Ohio, with blooming, bar and other mills recently placed in service. A large number of men are being employed who have been idle for many months past.

Magnesia—The Keasbey & Mattison Co., Ambler, Pa., is arranging for the early resumption of operations at its local plant, closed for some time past. Initial production will be on a 5-day, full-time, day-and-night-shift basis.

Kelp Plant May Be Sold

The Bureau of Soils has informed the appropriations committees that negotiations are pending for the sale of its kelp plant at Summerland, Ca. While the sale has not been consummated, the opinion is expressed that the plant will be disposed of during the current fiscal year.

Vulcanization of Rubber Discussed at Meeting of Delaware Section, A.C.S.

Dr. H. L. Fisher, chemical director of the B. F. Goodrich Co., addressed the Delaware Section of the American Chemical Society on Wednesday evening, Dec. 21. His subject was "Rubber Chemistry, Particularly Vulcanization and Its Acceleration," and the lecture was illustrated with slides and experiments. The sources of crude rubber were described and statistics as to the production and consumption of rubber were presented, showing that, of the world's total production, 76 per cent goes into tires and tubes; 67 per cent is imported into the United States and 50 per cent goes to Akron, Ohio.

The work on the structure of the rubber molecule was reviewed briefly and the speaker stated that the consensus at present favors the structure $(—CH_2—C(CH_3)=CH—CH_2—)_x$. It is believed that an indeterminate number of these chains are polymerized to form complex rings, with one double bond for every five carbon atoms.

The process of vulcanization is essentially the addition of sulphur to the rubber molecule, but the mechanics of the reaction are not thoroughly understood. In the hot process, sulphur is mixed with the rubber and heated to a temperature of 135 to 150 deg. C. In the cold process, the rubber is treated with a dilute solution of sulphur monochloride in some organic solvent, such as benzene. In the recent Peachey process, the rubber is treated with a mixture of sulphur dioxide and hydrogen sulphide at the ordinary temperature. In any case the amount of sulphur added is determined by the use to which the product is to be put. It is possible to add as much as 32 per cent of sulphur, corresponding to one atom of sulphur for each double bond in the rubber molecule. Ordinarily not more than 6 to 7 per cent of sulphur is added. The vulcanization process is still controlled by rule-of-thumb methods.

It has been known for many years that the use of such inorganic materials as litharge, magnesia, slaked lime and certain iodides would hasten the reaction between sulphur and rubber. In 1906 A. H. Marks used aniline and thiocarbanilide in vulcanization, and since 1910 many other organic accelerators have been introduced. One reason for this has been the development of synthetic rubber, which is much more difficult to vulcanize than the natural product. Among the many accelerators used may be mentioned pyridine, hexamethylenetetramine, p-nitrosodimethylaniline, dithiocarbamates, zinc xanthate and other basic compounds. Any acidity, even that of phenols, is harmful. The action of these accelerators is not well understood. They apparently act as sulphur carriers, and as such they may be considered as catalysts.

Sugar Refining Studied by Chemistry Students of University of Texas

Students of the senior class of the chemistry department of the University of Texas, Austin, are giving concerted attention to sugar refinery operations as found in regular plant practice. Weekly visits are being made to the plant of the Imperial Sugar Co., Sugarland, Tex., for investigation work, and reports are made after each trip covering the situation as found. Two students make the trip each week and expenses are defrayed by the state; in this way practically the entire class will be enabled to gain the practical experience thus afforded. Special experiments are being made to determine the best methods for saving sugar cane from early fermentation, and to elminate damage from the cane borer. The sugar is analyzed carefully and the various properties are studied by the students, and the industry is considered, as well, from other standpoints. Reports on the findings are made to the state.

Census of Coal-Tar Chemicals Extended to Include Other Organic Chemicals

The United States Tariff Commission has extended its census of coal-tar products to other organic chemicals, including the aliphatic group. The Synthetic Organic Chemical Manufacturers Association was instrumental in convincing the commission that the compilation of production figures of other organic chemicals would be particularly serviceable at this time.

Portland Cement Production Rate Decreases During November

The production of portland cement continued on a large scale during November, approximately 8,921,000 bbl. of finished cement having been manufactured. This quantity represents a decrease of 1,585,000 bbl. as compared with the record production of October, 1921, but is larger than that for any other month of this year up to May and is about 17 per cent greater than the average for November, 1917-1921. The total production for the 11 months ended Nov. 30, or 91,734,000 bbl., was about 99.5 per cent of the record quantity made during the corresponding period of 1920 and was 11 per cent greater than the average for the first 11 months of the years 1917-1921. Favorable operating conditions are indicated by this large production, the decrease having been due mainly to the slowing up of orders during the month.

The statistics shown in the following table, prepared under the direction of Ernest F. Burchard, of the United States Geological Survey, are based mainly on reports from producers of portland cement and in part on estimates. They indicate that even though the output for December should not quite equal that for November, the totals for 1921 would come very close to those for 1920 and thus constitute one of the highest outputs on record.

PORTLAND CEMENT STATISTICS, FIRST 11 MONTHS, 1921

Month	Production Bbl.	Shipments Bbl.	Stocks at End of Month Bbl.
January	4,098,000	2,539,000	10,300,000
February	4,379,000	3,331,000	11,400,000
March	6,763,000	6,221,000	12,000,000
April	8,651,000	7,919,000	12,660,000
May	9,281,000	9,488,000	12,450,000
June	9,296,000	10,577,000	11,150,000
July	9,568,000	10,301,000	10,414,000
August	10,244,000	12,340,000	8,280,000
September	10,027,000	11,329,000	6,953,000
October	10,506,000	12,114,000	5,348,000
November	8,921,000	5,195,000	9,091,000
	91,734,000	91,354,000	.....

Forest Products Laboratory Requires Increased Appropriation

For more than 10 years the Forest Products Laboratory at Madison, Wis., has been studying wood, always with the object of developing its most efficient and economical use. During that period it has amassed a great deal of scientific information of the most practicable application. Considerable credit is conceded the laboratory for its research accomplishments, but in the final analysis the value of its work must be measured by the extent to which the results of its work are made known and effectively applied by the wood-manufacturing industries. It is believed that this phase of the work is not being developed to an extent which its research results and industrial needs justify.

It is well recognized that those in charge have been endeavoring to remedy this situation, as evidenced by the information disseminated currently through trade and technical publications, by direct distribution of technical notes, by instructional courses in box construction and kiln drying, and in the facilities offered for direct co-operation in applying its information to specific manufacturing problems. In order to develop its dissemination work even to this extent, it has been necessary in certain cases to require co-operators to bear the cost of dissemination. This of necessity limits the broad usefulness of the laboratory and tends to restrict its information and services to the relatively few individuals and companies which are conversant with its work and the value of its results.

This is a situation which ought not to exist. It is one easily remedied, and the remedy lies in a specific appropriation by Congress for the dissemination and application of the results commensurate with its research activities and accomplishments.

The application of research is largely a matter of education, and when research is conducted as a governmental activity, adequate facilities must be provided for carrying the results through to their commercial application. This seems so thoroughly established as to forego argument. In its agricultural research and development the Department of Agriculture has solved the problem in a highly satisfactory and profitable way by placing county agents in every state in the Union, whose duties are to advise and educate the farmers in better methods of farming.

There is at Madison a great deal of information which it has never been possible to supply to the industries, because the finances are not available to put this information in usable shape for the business man. There should be an adequate force to prepare all data of practical application in a form which the business man can readily grasp and apply. In addition, men are needed whose whole time may be devoted to field work. The duties of these men should be to carry the information, now available and being made use of by the relatively few, to the men in the sawmill, or in the lumber yard, or in the wood-using plant. Personal contact is an effective means of disseminating practical, scientific information.

As concrete examples of some of the ways by which the dissemination of this knowledge should be developed, the following may be mentioned: expansion of instructional work in kiln drying, box construction, and special co-operative tests under a plan by which the expense is at least shared equally by the government and the co-operator; the assignment of field representatives to disseminate results in such fields as the preservation of mine timbers, the kiln drying of lumber, the proper working values of wood in building codes, the protection of wood pulp and pulpwood from decay in storage; and the demonstration of improved processes on a commercial scale, such as the cooking and bleaching of Southern pine for magazine and book paper, increasing the yield of methanol in destructive distillation, the utilization of sawdust and mill waste for cattle feed, and the de-inking of old magazines and newspapers.

The current annual appropriation for forest products research amounts to $325,000. This is equivalent to less than 25c. for every $1,000 of raw manufactured value for the total annual cut of wood. On the other hand, the Department of Agriculture is spending for agriculaural research and development $1.50 for every $1,000 of value of all agricultural and animal products.

The service above outlined requires a $100,000 increase in the appropriation. The Secretary of Agriculture and the director of the budget have approved $340,000 for the research work of the laboratory for the fiscal year beginning July 1, 1922. These estimates will be presented to Congress. They are contained in the estimates for the Forest Service, U. S. Department of Agriculture, and will be considered first by the sub-committee on agriculture of the House Committee on Appropriations and later by the Senate Committee on Agriculture. Sidney Anderson of Minnesota is chairman of the House sub-committee.

Slight Decrease in Unemployment in New York

The New York Committee on Unemployment Statistics reports that on Dec. 15 there were 331,000 unemployed persons in that city. This is about 13 per cent of number of persons reported by the federal census to have been gainfully employed on Jan. 1, 1920. On Oct. 17 the committee had reported 343,000 persons out of work, or 13.5 per cent of the total with gainful occupation.

The number of persons so employed in New York City on Oct. 17 and Dec. 15, as classified by groups, follows:

Group:	With Gainful Occupation January, 1920 Number	Per Cent	Approximate Unemployment as of Oct. 17, 1921 Number	Per Cent	Dec. 15, 1921 Number	Per Cent
Manufacturing and mechanical industries	951,889	37.6	143,071	15	173,840	18
Clerical occupations and trades	793,966	31.4	72,996	9	39,309	5
Domestic and personal service	306,069	12.1	26,940	9	23,900	8
Transportation	242,447	9.6	63,000	26	58,900	24
Professional service	168,375	6.7	26,940	16	24,774	15
Public service	61,084	2.4	9,163	15	9,163	15
All other occupations	7,919	3	1,029	13	1,029	13
	2,531,747	100	342,860	13.5	330,915	13

The greatest increase in unemployment has occurred in the building trades, which include about 125,000 workers, listed under "manufacturing nd mechanical industries." This has resulted from seasonal conditions.

Contractor Interested in Muscle Shoals

C. C. Tinker, president of the Construction Company of North America, the contracting concern constructing the Hetch Hetchy tunnel in California, has an appointment with the Secretary of War on Jan. 5 to discuss Muscle Shoals. While considerable publicity has been given to the statement that Mr. Tinker has hopes of submitting a more attractive offer than that of Henry Ford, the details of his plan have not been announced. It is stated that the government is to be relied upon for at least a portion of the financing.

To Discuss Fertilizer Matters in Conference at Department of Agriculture

Research and educational problems in the fertilizer industry are to be discussed on Jan. 6 at a conference at the Department of Agriculture. At that time the soil improvement committee of the National Fertilizer Association will meet with the department's officials who are interested in fertilizers for a general discussion of the present situation. It is the first meeting of the kind with the federal department, although the soil improvement committee has arranged similar conferences on several occasions at state agricultural colleges and at state experiment stations.

British Industries Fair to Be Held in London and Birmingham

Since its inception in 1915 the British Industries Fair has grown until it is today the most import national trade fair in the world. For the 1922 fair, to be held Feb. 27 to March 10, it has been possible to obtain enough additional accommodation both in London and Birmingham not only to provide for the annual growth of the fair but also to find room for the great industries which have hitherto exhibited at Glasgow. Textiles will, however, not be included in the 1922 fair.

The function of this fair, which is organized by the Department of Overseas Trade, is to bring buyer and seller together and to facilitate business between them by every legitimate means. Participation is confined to manufacturers and admittance is restricted to trade buyers, so that business is not impeded by crowds of sightseers.

The London section of the fair will, as in 1921, be housed in the White City, an enormous range of exposition buildings within a few minutes of the center of London, while the Birmingham section will again be in the great buildings of the Castle Bromwich Aërodome, within easy reach of the center of the city. Further imformation can be obtained from the Trade Department of the British Consulate-General at New York.

Imports of Chemicals Decrease in November, but Exports Increase Slightly

Further decreases in the imports of chemicals were registered in November, it is shown by the figures just compiled by the Bureau of Foreign and Domestic Commerce. The decrease applies to chemicals on the free list as well as those on the dutiable list. The aggregate value of the free-list chemicals imported during November was $3,983,567. This compares with $4,342,505 in October and $10,914,341 in November of 1920. The value of the dutiable chemicals imported in November is given as $2,085,144. This compares with $2,785,348 in October, and $4,639,186 in November of 1920.

The value of all chemicals exported in November was $4,938,494. This is a slight increase over October, when the value of exports totaled $4,671,310. It is a great decrease, however, from November, 1920, when exports totaled $12,894,772. A comparison of some of the items which make up these totals is as follows:

	Nov., 1920	Nov., 1921
Dyes and dyestuffs	$2,310,751	$500,918
Acids	506,379	76,744
Extracts for tanning	165,389	99,445
Total sodas	1,961,519	708,364

The imports of coal-tar products dropped from $2,107,682 in November, 1920, to $509,550, in November of this year. The value of the gums imported in November of this year was $1,756,868. This compares with $3,252,296 in November of 1920. That a part of this decrease is represented by shrinkage of value is shown by the fact that there was 7,294,528 lb. of the various gums imported in November of this year, whereas 9,228,269 lb. was valued at the much higher figure in 1920. An indication of the trend of color imports may be had from the following table:

	Nov., 1920	Nov., 1921
Germany, lb.	353,099	47,758
Switzerland, lb.	109,421	131,872
United Kingdom, lb	44,705	15,384
Other countries, lb.	55,411	4,473

Personal

WILLIAM J. BURGESS, formerly associated with the National Aniline & Chemical Co. in its production of resorcinol, has assumed the duties of chemical supervisor of the resorcinol plant of the Pennsylvania Coal Products Co., at Petrolia, Pa.

ROBERT E. DEVINE, formerly with the Joslin Smith Co., Cincinnati, Ohio, and more recently doing independent consulting work, has become associated with the Armour Soap Works in Chicago, where he is carrying on special investigation work on plant processes.

Dr. H. L. FISHER, chemical director of the B. F. Goodrich Co., Akron, Ohio, addressed the members of the Delaware Section of the American Chemical Society, Dec. 21, on "Rubber Chemistry."

F. G. JACKSON has been added to the chemical staff at the Bureau of Mines ceramic station at Columbus, Ohio. Mr. Jackson has been working as a physical chemist at the submarine base at New London, Conn.

Dr. FRANK E. E. GERMAN, of the University of Colorado, read an instructive paper on Nov. 28 on "Thermal Analysis as a Method of Discovering New Compounds" before the Colorado Section of the American Chemical Society. Dr. German spoke particularly of the hydroxides of uranium.

Prof. R. G. GUSTAVSON, of the University of Denver, read a paper Dec. 13 before the Teknik Club of Denver on "Colloids."

ERNEST LERICHE, formerly with the Newport Chemical Co. at Milwaukee, has become associated with Schaar & Co., Chicago.

JAMES H. POST has been elected president of the Cuban-American Sugar Co., New York, N. Y., succeeding Robert B. Rawley, deceased.

A. E. SCHAAR, of Schaar & Co., Chicago, will sail for Holland Jan. 4. He expects to visit the principal cities of Europe.

R. B. STRINGFIELD, who has been chemical engineer for the Los Angeles plant of the Goodyear Tire & Rubber Co., has been transferred to the parent plant at Akron, Ohio, in connection with chemical engineering development there.

A. P. VANGELDER announces that in January he will retire from the active ranks of the organization of the Hercules Powder Co., where he has been general superintendent.

Obituary

JOHN C. PENNIE, senior member of the firm of Pennie, Davis, Marvin & Edmonds, patent attorneys, died in New York City on Dec. 23, 1921. A more extended notice will appear in a subsequent issue of this magazine.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

What We Hope to Accomplish in Our Market Pages

Reference has already been made in the editorial columns of this issue to the magazine's plans for extending the scope of its usefulness and thus increasing the service it is able to render to its readers. It is believed that one of the ways in which this purpose can be served is through the market pages, since they represent already established contact with commercial factors in the chemical and allied industries. By broadening the conception of these pages to include the discussion of market conditions and of those economic and business problems that have important bearing on trade and commerce in chemicals, it is hoped to present information of value to the chemical engineer and technical executive as well as to the man engaged in the actual buying and selling of chemical products.

The weekly price quotations which have become one of the features of CHEM. & MET.'S service to the industries are to be continued, and no effort will be spared in making them accurate, trustworthy indexes of business in the chemical and allied industrial markets. The market letters from New York and other centers of trade and commerce are to be written from this broader viewpoint in order to reflect national as well as local conditions in these markets. From time to time these columns will contain brief reviews of business, commerce and finance and of the relation to the chemical industry of such important factors as the tariff, taxation, foreign exchange and international trade. It is hoped that space can be given occasionally to pertinent industrial notes and reports from individual firms whose activities influence or have a marked effect upon conditions in the chemical market. In a word, then, it is our intention to make these pages a source of interesting and reliable commercial information, and to this end it is hoped that we may have the co-operation of all who are interested in advancing the best interests of the chemical, metallurgical and related industries.

Some High Spots in Business During 1921

The outstanding characteristic of business during the year just past has been the reaction toward certain economic tendencies and developments. Prominent among these has been the world-wide process of deflation and the gradual return to a mythical state of normalcy. Although the process has not yet been completed and further readjustment appears to be inevitable, the chemical industry has at least kept pace with the general trend of liquidation. Price indexes of the government and other agencies place chemicals on a level only slightly higher than the average for all commodities. Indeed, many basic chemicals are being offered at prices which are less than pre-war costs.

Falling prices, both in this country and abroad, have had a demoralizing effect on business. International trade has been seriously affected by this element of uncertainty, although it is believed that in some cases the apparent decreases may have been caused by lower unit costs. This point is well illustrated by a comparison of our present export trade with that of the pre-war period and of 1920. A quantity survey recently completed by the U. S. Chamber of Commerce shows that "of the twenty exports that are of the greatest tonnage, fifteen registered increases in poundage ranging from 43 to 5,210 per cent for the first 9 months of 1921, as compared with the 9 months average for the pre-war period, 1910 to 1913. Losses on the five other commodities were from 5 to 32 per cent." Furthermore, over half of these commodities have been exported in larger tonnages during 1921 than during the corresponding period of the preceding year.

An equally important factor in shaping the year's business has been the fluctuations in foreign exchange. In a subsequent issue it is our intention to present a detailed study of the trend of the principal currencies of the world, but for the purpose of the present review it is perhaps sufficient to direct attention to two outstanding examples. The German mark, which 6 months ago was worth 1.5c., fell to 0.35c. during November. On the other hand, there is the phenomenal recovery of the pound sterling from $3.53 in January, 1921, to $4.24 early in December.

POLITICAL DEVELOPMENTS—TAXATION AND THE TARIFF

Political developments of the year have been disappointing on the whole, although in a few instances they appear to have taken a somewhat favorable turn. The Disarmament Conference may not accomplish all that might be desired, but it must be admitted that it has effected savings which will ultimately benefit industry. The new revenue law has also been the source of some disappointment. Instead of offering a new and constructive solution for our tax problems, the old war revenue act has been patched up and overhauled for additional service. Some consolation, however, is gathered from the repeal of the excess profits tax which is effective Jan. 1, 1922, in the reduction of the levy on capital gains and in the repeal of the transportation and other of the so-called "nuisance" taxes.

The tariff, although figuring prominently in the political developments of the year, can scarcely be said have had a beneficial influence on industry. In fact the year witnessed a rather general change in the attitude of many manufacturers toward the tariff. There appeared to be a growing feeling that the time was inappropriate for tariff framing and that little practical assistance could be obtained from such legislation. The inorganic chemical industry has had to meet a great deal of foreign competition, which in a number of instances has proved disastrous to the domestic producers. The dye and organic chemical industries, on the other hand, have been less affected, largely because of the continued control of imports provided by the dye and chemical section of the emergency tariff act.

The important lesson taught by the year, however, has been to emphasize the absolute necessity for increasing plant efficiencies and thus lower production costs. The period of retrenchment and careful, competent management must continue despite the few signs of encouragement that are gradually making their appearance. Inventories, both of raw materials and finished products, must be reduced, costs brought down and every preparation made for a severe, competitive fight for business. It is in this direction that future advance must be made. Economies of production, rather than expanded volume, promise greatest profits for business during 1922.

Growing Demand for Zinc Compounds

The increased production of rubber tires, with corresponding greater consumption of zinc oxide, has resulted in a growing demand for chemical derivatives of zinc. At the present time about 50 per cent of the zinc production is being used by the chemical trades, while the other 50 per cent is divided among the brass, galvanizing, sheet zinc and affiliated industries. This compares with averages of 25 and 75 per cent, respectively, in former years.

A Review of the Chemical Market During 1921

During the closing months of 1920 there was a widely prevalent feeling that the chemical and allied industrial markets would show evidence of marked improvement durthe first 3 months of 1921. Unfortunately this revival was not effected. Liquidation continued throughout the entire year and business reversals were more common in the chemical industry than ever before. Our newly developed export trade in chemicals practically disappeared during the early part of the year as foreign exchange sank to depths at which competition was impossible. Only recently, however, Japan and certain South American countries have turned their attention to the American market and have placed orders for large tonnages of phenol and various other general chemicals. During the later months of 1921 Italy has also been a frequent buyer and domestic manufacturers of caustic soda have reported business to this country in as large as 1,000-ton lots.

COMPARATIVE PRICES OF 45 IMPORTANT CHEMICALS, JANUARY, 1921–JANUARY, 1922

Article	Unit	Jan., 1921	April	June	Oct.	Jan., 1922
Acetic acid, glacial	Lb.	$0.10½	$0.09½	$0.09¾	$0.10	$0.10
Muriatic acid, 20 deg.	Lb.	.01¾	.01½	.01¼	.01½	.01½
Nitric acid, 40 deg.	Lb.	.07	.06½	.06½	.06¼	.06¼
Oxalic acid	Lb.	.18½	.17	.18	.15½	.14½
Sulphuric acid, 66 deg.	Ton	21.00	19.00	18.00	17.00	17.00
Acetate of lead	Lb.	.13⅜	.11⅝	.11⅝	.10⅝	.10⅝

The import business for the first 6 months of 1921 progressed exceptionally in the face of many adverse conditions. German interests, aided by the low mark, shipped goods into the American market at prices lower than domestic costs. The latter part of the year has been different to some extent. Imports of chemicals have shrunk noticeably. In October, 1921, the value of arrivals was $7,127,853, as compared with the corresponding month of 1920, which was $19,192,039. This represented a drop of over 60 per cent. The value of September, 1921, imports was much less—$6,506,192. The past year showed some rather striking advances in imports and as many exceptional decreases. Naphthalene and coal-tar intermediates dropped over 60 per cent. Fusel oil, crude camphor and potassium cyanide lost over 70 per cent. Carbonate of potash fell from 16,313 tons to 2,898 tons; sodium nitrate from 581 to 174 long tons. Miscellaneous coal-tar crudes dropped over 90 per cent.

Some of the advances were equally marked. Calcium salts advanced over 10 per cent; sodium cyanide, 25 per cent, miscellaneous potassium salts, 60 per cent. Caustic potash rose from 778 to 3,908 tons, bleaching powder from 495 to 4,581 tons, benzene from 104 to 820 tons. To counterbalance the last two items, we exported 6,408 tons of bleach and 32,280 tons of benzene.

In general, the American chemical industry has undoubtedly just passed its most trying crisis. The industry has been severely dealt with and the new year will put it to a further test. Although there were many setbacks during the 12 months of depression, the results have not been disastrous. The encouraging feature of our industry is that everybody in the trade is hopeful and optimistic. The future is not without hope and everyone in trade circles is determined to fight hard to overcome the business depression that has proved so disastrous to some of the domestic producers.

Mathieson Alkali Works Reports Encouraging Business Conditions

E. M. Allen, president of the Mathieson Alkali Works, in a letter to the stockholders states that while general business is still unstable, that of the company shows material improvement during the last 3 months and appears to justify a hopeful outlook for the future. The output of the Niagara plant has gradually been increased until it is now approximately 80 per cent of capacity. During the recent inactivity, arrangements were made to increase materially the output of certain profitable products to replace others whose manufacture and sale have proved less profitable. The Saltville works of the company are operating at only about half capacity, but, as pointed out in Mr. Allen's letter, "because of improved physical and management conditions, the production substantially equals the average output of the entire plant during the past 9 years."

Regarding trade conditions in the alkali industry, Mr. Allen points out that "although competition has been unusually keen and average selling prices have gradually decreased, the company's position is believed to be fairly secure because of many new contracts made for 1922 delivery and a considerable tonnage which will be carried over under 1921 contracts, and it is believed that lower cost of production will keep pace with decreased selling prices."

The New York Market

NEW YORK, Dec. 30, 1921.

There were but few developments in the chemical market during the past week, owing to the holidays and the slow season of the year. However, those close to the heart of industry believe that the latter part of January will see a marked revival in the general list, with prices more stabilized. An important announcement by the domestic manufacturers of *sodium cyanide* that a reduction of 4c. per lb. would become effective Jan. 1 came as a considerable surprise to the trade, since foreign material has been held firm by a majority of the resale trade.

Another outstanding feature of the industry is the continued rise of *yellow prussiate of soda*. Some believe the advance of foreign exchange has had a strengthening influence on this commodity, while others contend that the natural working of the law of supply and demand has made prices firm. Prices opened at 16c. per lb. and closed with the majority of dealers asking up to 17¾c. per lb. Still another item that commanded attention was *caustic potash*, 88-92 per cent, on which spot prices advanced noticeably, even though large tonnages of imported material have already been docked. These lots, in most cases, had been previously consigned to various domestic consumers. The present market ranges from 6@6¼c. per lb., ex-store New York. Solid *caustic soda* has not attracted new consumers, and business in this commodity will be dull until the latter part of January. Leading producers report a large part of their output already sold on contract over 1922 at $2.75 per 100 lb., f.o.b. works, basis 60 per cent. Spot prices range from $3.80@$4 per 100 lb., f.o.b. or f.a.s. New York. Small-lot trading has featured the market on *bichromate of soda* and sales were made at 7⅞c. per lb. In some quarters it was intimated that round-lot business would shade prices down to 7¾c. per lb. Demand has not been active, but supplies in resale quarters are not abundant and prices seem

to be well in line with manufacturing costs. *Yellow prussiate of potash* advanced in sympathy with prussiate of soda. Although the demand cannot be termed active, spot supplies are rather scarce and prices are quoted firmer at 24@25c. per lb., according to quantity. The red prussiate has also been advanced, and prices range from 30@30½c. per lb. *Light soda ash* has been in moderate demand during the week and prices were slightly firmer. Imported material was quoted around $1.80 per 100 lb., ex-dock. Domestic material in single bags ranged from $2@$2.10 per 100 lb.

The Chicago Market

CHICAGO, Dec. 30, 1921.

Trading in industrial chemicals during the past 2 weeks has been slow. No one expects a revival of even fair business until after the first of the year. With reference to prices there was little of real importance done over this period and most factors are holding to the idea that business could not have done during these last weeks of the year at any reasonable scale of prices. The only reports of shading came from weak holders and these offers failed to disturb the market to any great extent. All factors are generally optimistic over the prospects for next year and in some quarters are preparing for a considerable increase in both inquiries and actual business.

The alkali market is very quiet at the present and prices are slightly easier. *Caustic soda* was offered today at $4 per 100 lb. for the solid 76 per cent and the ground at $4.65@$4.70 in ton lots. There is little material moving, as deliveries on 1922 contracts will soon start and then low prices are predicted for the coming year. *Caustic potash* is quiet and unchanged at 6½c. per lb. for the 88-92 per cent material. Soda ash lacks quotable change in first hands and is moving only in small parcels at $2.60 per 100 lb. basis cooperage.

Supplies of *potash alum* are rather light and 6c. per lb. for the lump and 6½c. for the powdered were the best offers noted. *Aluminum sulphate* is quiet at $3.25 per 100 lb. for the iron free. *White arsenic* was reported to be moving in a fair way at 6¾@7c. per lb. *Bleach* is quiet at 3@3¼c. per lb. for large drums. Another advance on *glycerine* was announced by refiners, which brings the c.p. material to 16c. per lb. drum basis. This item is one of the very few which is apparently enjoying a good demand. Single *nickel salts* is also in good demand and the price is firm at 12@13c. per lb.

Potassium bichromate is still slow, with supplies plentiful at 13@13½c. per lb. *Bichromate of soda* has assumed a firmer position and it was impossible to do better than 9¼c. for material of standard brand. *Chlorate of potash* is scarce on spot and 8½@9c. were the prevailing quotations for the powdered. Spot stocks of the crystals could not be located and 10c. was the best offer on material for shipment from the East. The *prussiates of potash* are both firm and scarce. The red crystals are held for 30c. per lb. in small lots and the yellow at 25c. *Salammoniac* is firm with supplies none too plentiful. Holders are asking 8@8½c. for the white granular in large casks and are said to be doing a fair volume of business. The condition of the acid market remains unchanged and may be characterized as very dull.

The Iron and Steel Market

PITTSBURGH, Dec. 30, 1921.

The year now ending has been the smallest for steel production since 1905, production of steel ingots being not over about 20,000,000 gross tons, so that the industry had, in a sense, a setback of 16 years, which is a new record. The setback in point of tonnage was also a new record, about 55 per cent from the record tonnage, made in 1917, 43,619,200 tons.

The year 1921 opened with steel ingot production at the rate of about 30,000,000 tons, although a rate of about 42,000,000 tons had been maintained during the first 9 months of 1920, before the tapering off began. Production decreased almost continuously until at the middle of July the rate was barely over 10,000,000 tons a year. Then improvement began, carrying the rate up to about 25,000,000 tons at the beginning of November. To the end of the year there was some falling off, but the rate even now, despite holiday dullness, is probably above 20,000,000 tons, and a return to a rate of 25,000,000 tons within a few weeks, or 2 months at the outside, is far from improbable.

STEEL CONSUMPTION

Almost invariably when the steel appears scarce and prices are high it is remarked in the trade that there are no stocks of consequence and that liquidation will therefore be easy, but in every instance the event has proved that the stocks existed. Even 1920, with an apparent scarcity indicated by the fanciest prices in the whole history of the industry, has proved no exception. At the beginning of 1921 there were stocks of steel in the hands of buyers, both jobbers and manufacturing consumers, and there were stocks of manufactured wares, including agricultural implements, machinery, hardware, tools, etc., in the hands of manufacturers and distributers. All these stocks had to be liquidated, and it was chiefly the process of liquidation that caused steel production to fall to its extremely low level in July. An incident was that in the early months of the year customers of the United States Steel Corporation took larger tonnages of steel than they currently needed.

PRICES DURING 1921

The last day of 1920 had seen the disappearance of the last extra price on the part of independents. All independents had advanced prices above the Steel Corporation level in 1920, the corporation alone adhering to the Industrial Board schedule, promulgated March 21, 1919. Late in the year independent prices began to drop to the corporation level, pipe being the last. During January there was a steady market. Early in February independents got on the other side from the one they occupied in 1920, and began cutting the Steel Corporation's prices. In April the corporation reduced and from that time on there was only one market, quite an irregular one. On the whole the Steel Corporation, on account of the good will acquired by its price policy in 1920, was able to obtain slightly higher prices, on an average, than the independents, but the difference was only a dollar or two a ton, while in 1920 the difference the other way was frequently $10 or $20.

Two-thirds of the total decline in steel prices in 1921 occurred in the 6 months from Feb. 1 to Aug. 1, when the market experienced a succession of falls. Afterward there was only a gentle sagging now and then, with attempts, rarely successful, at recovery. A weighted average of all the important finished steel products showed 3.25c. at the beginning of the year and 2.16c. at the end, a decline of about $22 per net ton, or just one-third, and putting prices at a level 26 per cent above the average of 1913 and 52 per cent above the low level of December 31, 1914.

THE MARKET FOR THE WEEK

The steel market has been extremely quiet in the past week, reflecting the usual holiday or pre-inventory dullness. The quietness has given no concern to producers or buyers, being regarded as altogether natural. The market really lost most of its snap about the middle of October, the remarkable thing being that production held up so well notwithstanding the dullness of the market.

As noted in our last report the Steel Corporation reduced its prices on wire products $5 a ton, this following a reduction a week earlier in tubular goods, each reduction having been made on account of price cutting by independents. In the past week nothing has occurred as to steel prices, which are fairly steady. The liquidation has been quite thorough and no further changes of any consequence are to be expected for some time to come. The next change worth mentioning may come by buyers being ready to make purchases for forward deliveries, in which case some slight extra concessions may be brought out.

Four contracts for Connellsville furnace coke for the first quarter of the new year have been made, at prices ranging from $3.25 to $3.50, the variation being probably due chiefly to quality. The spot market is very soft, with $3 scarcely even an asking price.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.10 — $1.15
Alpha-naphthol, refined	lb.	1.25 — 1.30
Alpha-naphthylamine	lb.	.30 — .32
Aniline oil, drums extra	lb.	.17½ — .19
Aniline salts	lb.	.24 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.35 — 1 45
Benzidine, base	lb.	.90 — 1.00
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.27 — .32
Benzene, 90%, in drums (100 gal.)	gal.	.25 — .28
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.70 — .75
Beta-naphthol, tech	lb.	.30 — .34
Beta-naphthyla mine, sublimed	lb.	1.65 — 1.75
Cresol, U. S. P., in drums (100 lb.)	lb.	.15 — .16
Ortho-cresol, in drums (100 lb.)	lb.	.24 — .26
Cresylic acid, 97–99%, straw color, in drums	gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums	gal.	.65 — .70
Cresylic acid, 50%, first quality, drums	gal.	.45 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.95 — 1.10
Dimethylaniline	lb.	.40 — .45
Dinitrobenzene	lb.	.23 — .27
Dinitroclorbenzene	lb.	.20 — .25
Dinitronaphthalene	lb.	.30 — .35
Dinitrophenol	lb.	.35 — .40
Dinitrotoluene	lb.	.25 — .30
Dip oil, 25%, car lots, in drums	gal.	.30 — .35
Dipnenylamine	lb.	.60 — .70
H-acid	lb.	1.00 — 1.10
Meta-phenylenediamine	lb.	1.10 — 1.15
Monochlorbenzene	lb.	.12 — .14
Monoethylaniline	lb.	1.65 — 1 70
Naphthalene crushed, in bbls.	lb.	.07 — .08
Naphthalene, flake	lb.	.07 — .08
Naphthalene, balls	lb.	.08 — .09
Naphthionic acid, crude	lb.	.70 — .75
Nitrobenzene	lb.	.12 — .15
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	3.00 — 3 10
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.77 — 80
Ortho-nitro-toluene	lb.	.15 — .20

Ortho-toluidine	lb.	.20 —	.25
Para-amidophenol, base	lb.	1.40 —	1.45
Para-amidophenol, HCl	lb.	1.70 —	1.80
Para-dichlorbenzene	lb.	.12 —	.15
Paranitroaniline	lb.	.77 —	.80
Para-nitrotoluene	lb.	.80 —	.85
Para-phenylenediamine	lb.	1.70 —	1.75
Para-toluidine	lb.	1.25 —	1.40
Phthalic anhydride	lb.	.37 —	.40
Phenol, U. S. P., drums	lb.	.11½ —	.15
Pyridine	gal.	2.00 —	3.50
Resorcinol, technical	lb.	1.50 —	1.60
Resorcinol, pure	lb.	2.00 —	2.25
Salicylic acid, tech., in bbls	lb.	.20 —	.21
Salicylic acid, U. S. P	lb.	.22 —	.23
Salol	lb.	.70 —	.72
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.16
Sulphanilic acid, crude	lb.	.27 —	.30
Tolidine	lb.	1.30 —	1.35
Toluidine, mixed	lb.	.43 —	.45
Toluene, in tank cars	gal.	.25 —	28
Toluene, in drums	gal.	.28 —	.31
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices are quotably unchanged for the entire list.

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.30 —	5.35
Rosin E-I	280 lb.	5.40 —	5.50
Rosin K-N	280 lb.	6.05 —	6.75
Rosin W. G.-W. W	280 lb.	7.00 —	7.25
Wood rosin, bbl	280 lb.	6.25 —	.....
Spirits of turpentine	gal.	81½ —	.....
Wood turpentine, steam dist	gal.	.79 —	.....
Wood turpentine, dest. dist	gal.	.78 —	.....
Pine tar pitch, bbl	200 lb.	..... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	..... —	9.50
Retort tar, bbl	500 lb.	—	9.50
Rosin oil, first run	gal.	.36 —	.....
Rosin oil, second run	gal.	.39 —	.....
Rosin oil, third run	gal.	.46 —	.....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		$1.90
Pine oil, pure, dest. dist	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, bulk and double bags	100 lb.	$2.30 —	2.90
Blood, dried, f.o.b., N. Y	unit	4.00	
Bone, 3 and 50, ground, raw	ton	30.00 —	32.00
Fish scrap, dom., dried, f.o.b. works	unit	2.90 —	3.00
Nitrate soda	100 lb.	2.30 —	2.35
Tankage, high grade, f.o.b. Chicago	unit	2.75 —	3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	4.50 —	6.50
Tennessee, 78-80%	ton	8.50 —	9.00
Potassium muriate, 80%	ton	34.00 —	35.00
Potassium sulphate	unit	.90 —	1.00

Crude Rubber

Quotations have remained unchanged since our previous report.

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.10¾ —	$0.10¾
Castor oil, AA, in bbls	lb.	.11½ —	.12
China wood oil, in bbls. (f.o.b. Pac. coast)	lb.	.13¼ —	.13½
Coconut oil, Ceylon grade, in bbls	lb.	.09 —	.09¼
Coconut oil, Cochin grade, in bbls	lb.	.10 —	.10¼
Corn oil, crude, in bbls	lb.	.08⅝ —	.08¾
Cottonseed oil, crude (f. o. b. mill)	lb.	.07 —	.07¼
Cottonseed oil, summer yellow	lb.	.08¼ —	.09
Cottonseed oil, winter yellow	lb.	.09¼ —	.09¾
Linseed oil, raw, car lots (domestic)	gal.	.67 —	68
Linseed oil, raw, tank cars (domestic)	gal.	.62 —	.63
Linseed oil, in 5-bbl lots (domestic)	gal.	.70 —	.71
Olive oil, denatured	gal.	$1.15 —	$1.20
Palm, Lagos	lb.	.07½ —	.07¾
Palm, Niger	lb.	.06¼ —	.06¼
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08 —	.08¼
Peanut oil, refined, in bbls	lb.	.11 —	.11¼
Rapeseed oil, refined in bbls	gal.	.82 —	.83
Rapeseed oil, blown, in bbls	gal.	.88 —	.90

Palladium	oz.	55.00–60.00
Mercury	75 lb.	49.00–50.00

FINISHED METAL PRODUCTS AND OLD METALS

Quotations have remained unchanged since our previous report.

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named

	New York	Cleveland	Chicago
Structural shapes	$2.78	$2.88	$2.78
Soft steel bars	2.68	2.78	2.68
Soft steel bar shapes	2.68	2.78	2.68
Soft steel bands	3.28	3.48	3.28
Plates, ¼ to 1 in. thick	2.78	2.88	2.78

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

FORT SMITH—The Page Milling & Smelting Co. has leased property in Benton County, totaling over 500 acres of copper land, and plans for the construction of a new refining plant on a portion of the site. The initial installation will comprise a 150-ton concentrating plant and auxiliary buildings.

California

ANAHEIM—The Anaheim Sugar Co. is considering preliminary plans for the erection of a new mill, estimated to cost about $250,000, including machinery. D. Jessurun is president.

SAN FRANCISCO—The Pacific Sanitary Mfg. Co., 67 North Montgomery St., manufacturer of sanitary earthenware, is planning for extensions in its plant at Richmond, Cal., to cost about $60,000.

Delaware

WILMINGTON—The Wilmington Sugar Refining Co. is perfecting plans for the immediate erection of the first building at its new local plant at South Wilmington, to be followed by the construction of seven other plant buildings. The entire plant is estimated to cost close to $1,000,000.

Florida

ARCHER—The Maddox Foundry & Machine Co. is considering tentative plans for the erection of a 40 x 50-ft. addition to its foundry. H. Maddox is general manager.

Illinois

CHICAGO—The Oxweld Acetylene Co. has purchased the property it has been occupying under lease, at Jasper Place, near 37th St. The plant was acquired at an indicated $173,500.

Indiana

BLOOMINGTON — The Bloomington Brick & Tile Co., with headquarters at Indianapolis, is considering plans for the erection of a new brick, tile and other burned clay products manufacturing plant at Bloomington, estimated to cost about $200,000, including machinery. Work will be commenced in the spring. A. W. Beecher is president.

INDIANAPOLIS—The Piel Bros. Starch Co., 831 State Life Bldg., has awarded a contract to Latham & Walters, State Life Bldg., for a 1-story top addition at its plant, 200 x 200 ft., with improvements in the present factory, estimated to cost about $50,000. William F. Piel is president.

Iowa

DUBUQUE—The Globe Portland Cement Co., 416 McKnight Bldg., Minneapolis, Minn., has preliminary plans in preparation for the erection of a new cement-manufacturing plant at Dubuque, estimated to cost about $1,5000,000 for initial mills. The building contract has been awarded without competition to H. C. Stuchen, Dakota Bldg., St. Paul, Minn. The C. L. Pillsbury Co., 1200 Second Ave., South Minneapolis, Minn., is engineer.

Louisiana

BATON ROUGE—The Standard Oil Co. of Louisiana is planning to increase the capacity of its local refinery, including extensive storage facilities, comprising about 20 tanks, each with capacity of 55,000 bbl. The company is said to have purchased the plant of the Export Oil Corp., at Avondale, La., for a consideration of about $950,000, and will continue the operation of the refinery. Fire recently damaged a portion of the company's distributing plant on South Claiborne Ave., New Orleans, with loss reported at about $30,000.

Maryland

BALTIMORE—The United States Industrial Alcohol Co., Curtis Bay, has tentative plans under consideration for the erection of a new 1-story plant in the Stonehouse Cove section, 50 x 180 ft. It is said that work will be started in the spring.

Massachusetts

SPRINGFIELD—Fire recently destroyed a portion of the plant of the Fiberloid Co. No official estimate of loss has been made.

BOSTON—The Eastern Metal & Refining Co., 121 Beverly St., has taken out a permit to rebuild the portion of its foundry recently damaged by fire.

Michigan

KALAMAZOO—The Sanitary Mfg. Co., manufacturer of sanitary earthenware products, will build a new addition to its plant, 112 x 400 ft., estimated to cost about $200,000, including equipment. It is expected to have the extension ready for occupancy in the late spring, adding about 125 men to the working force for operation.

DETROIT—The Solvay Process Co. has completed plans for the erection of a 1-story addition to its local building, 22 x 50 ft., estimated to cost about $15,000. Maurice H. Finkel, 333 Majestic Bldg., is architect.

New Jersey

LINDEN—The Warner-Quinlan Co., 79 Wall St., New York, has plans under way for the erection of the second section of its new oil refinery and asphalt plant at Linden, estimated to cost about $1,000,000. The entire plant will cost about double this amount and will replace a works recently destroyed by fire. The Gifford, Huntze, Baker Engineering Corp., 40 Rector St., is engineer. Bids will be asked at an early date.

BELLEVILLE—Fire, Dec. 16, destroyed a portion of the plant of the Federal Leather Co., River Road, with loss reported at about $12,000.

JERSEY CITY—Colgate & Co., 105 Hudson St., manufacturers of soaps, etc., have construction under way on a new 3-story plant addition, 100 x 125 ft., with cost estimated at about $140,000. The Turner Construction Co., 244 Madison Ave., New York, has the erection contract.

New York

NEW YORK—The Goodyear Tire & Rubber Co., 123 West 64th St., with plant at Akron, O., is concluding negotiations with the Brazilian Government for permanent rights on certain state property, heretofore held under limited concessions, with site to be used for the erection of a large rubber-manufacturing plant. The project was planned a number of years ago, but has been held in abeyance owing to industrial conditions.

Oklahoma

PONCA CITY—The Chamber of Commerce is perfecting plans for the establishment of a local brick-manufacturing plant. A new company will be formed, it is said, to construct and operate the property.

HENRYETTA — The Henryetta Glass Mfg. Co. has acquired local buildings and plant site for the establishment of a new factory for the manufacture of glass specialties. Machinery will be installed and operations commenced at an early date.

TULSA—The Oklahoma Tanning & Mfg. Co. has acquired the plant heretofore occupied by the Pawpaw Refining Co., for the establishment of a new tannery. Machinery and equipment will be installed to provide for a daily output of about 250 tanned hides.

GRANITE—The Town Council is considering preliminary plans for the erection of a new municipal gas plant and distributing system. A bond issue will be arranged to cover the cost of the improvement.

Pennsylvania

POTTSTOWN—The Vulcweld Rubber Co. has acquired property, 300 x 392 ft., on West High St., to be used as a site for the erection of a new 2-story plant for the manufacture of automobile tires and other rubber products. It will be 60 x 260 ft., supplemented with a 1-story building for general operations and storage service.

PHILADELPHIA—Horace T. Potts & Co., 316-20 North Third St., manufacturers of iron and steel castings and other metal products, are perfecting details for the erection of their proposed new foundry buildings at Erie Ave. and D St., and will break ground for the structures early in the spring. The new plant is estimated to cost in excess of $150,000. The William Steele & Sons Co., 1600 Arch St., is the contractor. H. T. Potts is head.

PHILADELPHIA — The Pennsylvania Sugar Co., North Delaware Ave., has acquired additional property in the vicinity of its local refinery, 83 x 146 ft., adjoining other land lately acquired, to be used for proposed future expansion. The last purchase was acquired for a consideration of about $18,000.

CHESWICK—The Stonecrete Corp., 6023 Penn Ave., has commenced the erection of its proposed new plant at Cheswick, to be equipped for the manufacture of cement products. Charles B. Lawton heads the company.

Tennessee

CHATTANOOGA—The Crane Enamelware Co., occupying the former plant of the Mutual Enamelware Co., is arranging for a state charter with capitalization of $2,000,000, for the manufacture of enamelware products of all kinds. Increased production will be arranged in the line of sanitary ware, supplementing the present output of plumbing fixtures, etc. The company is headed by Hugh W. Powell and Frank H. Caldwell.

CHATTANOOGA—The Southern Cotton & Paper Co. has been organized by Mercer Reynolds and associates, Chattanooga, with capital of $200,000, for the erection of a new plant at Nashville, Tenn. A site has been acquired at that place and construction will be commenced at an early date. The plant will specialize in the manufacture of bond and kraft papers from cotton linters.

MEMPHIS—The Memphis Varnish Co., owned by the De Soto Paint Co., has let contract for the erection of a 2-story building to be used for a varnish plant at East Railroad Ave. and South Somerville St. The plant and the equipment represent an initial investment of about $50,000. New storage tanks will be installed to take care of between 250,000 and 300,000 gal. of liquid.

Texas

WORTHAM—The Wortham Refining Co., recently organized, has perfected plans for the immediate erection of a new oil-refining plant in the northern section of the borough. It is proposed to have the refinery ready for operation in from 60 to 90 days, with initial output of about 400 bbl. per day. The plant will be of one-unit type, and will be increased at a later date. H. G. Lemendes is president; and Roger Seeley, secretary and treasurer.

SANTA ANA—The Industrial Department of the Santa Fe Railway Co. is developing plans for the establishment of a local plant for the manufacture of glass products. The project will be carried out in conjunction with a new company to be organized, headed by F. E. Brazelton, Santa Ana.

EL PASO—The American Smelting & Refining Co., 120 Broadway, New York, is considering the erection of a large metallurgical experimental plant on local site for testing ores from its properties at Monterey, Mex.

MINERVA—The Owens Refining Co., First National Bank Bldg., Cameron, Tex., will construct its proposed new oil refinery in this section on a site acquired at Minerva. It will have an initial daily output of about 1,200 bbl. W. A. Jones is construction engineer for the company. John S. Owens is president and manager.

GAINESVILLE—The Lone Star Co. has commenced the erection of a new condensing plant with number of other buildings for a new works to produce gasoline from natural gas. It is planned to have the plant ready for operation early in 1922. It will cost about $75,000.

AMARILLO—The Panhandle Brick & Tile Co. has commenced operations at its new local plant, and will develop production in the line both of brick and tile from clays secured in this section. The plant has a rated capacity of 100,000 bricks per day.

Virginia

GRAHAM—The Columbia Chemical Co., Roanoke, Va., is perfecting plans for extensions and improvements in its plant at Graham. Work will be commenced at an early date.

West Virginia

WHEELING—The Wheeling Mold Foundry Co. has construction under way on a 1-story addition to its plant, 60 x 285 ft., estimated to cost about $50,000. It will be equipped as a roll shop.

Capital Increases, Etc.

THE WHITE TAR CO., 56 Vesey St., New York, N. Y., with plant at Kearny, N. J., has filed notice of increase in capital from $100,000 to $300,000.

THE HOOD RUBBER CO., East Watertown, Mass., has arranged for a note issue of $6,000,000, to be used for general operations, financing, etc.

THE MONARCH CHEMICAL CO., Saginaw, Mich., has filed notice of dissolution under state laws.

THE HEAT UNIT TILE CO., 616 Fidelity Bldg., Tacoma, Wash., has filed notice of increase in capital from $100,000 to $300,000. Frederick H. Murray heads the company.

Upon petition by stockholders, a temporary receiver has been appointed for the NEW MEXICO FIREBRICK CO., Gallup, N. M.

THE W. S. VICK CHEMICAL CO., Knoxville, Tenn., has filed notice of change of name to the Gilbert Chemical Co., at the same time increasing its capital from $100,000 to $250,000.

THE DETROIT INDEPENDENT OIL CO., Detroit, Mich., has filed notice of increase in capital from $25,000 to $150,000.

THE AJAX RUBBER CO., Trenton, N. J., has arranged for a bond issue of $3,000,000, the proceeds to be used for financing, general operations, etc.

C. BISCHOFF & CO., 451 Washington St., New York, N. Y., has filed notice of change of name to the Carbic Color & Chemical Co.

THE CONDENSED BLUING CO., 66 East South Water St., Chicago, Ill., has filed notice of increase in capital from $50,000 to $100,000.

THE STANDARD OIL CO. OF INDIANA, Indianapolis, has been granted permission by the Indiana Securities Commission to issue common stock for $40,000,000.

New Companies

THE IMPERIAL REFINING CO., Lock Haven, Pa., has been incorporated with a capital of $100,000, to manufacture refined oil products. S. H. Fredericks, Lock Haven, is treasurer.

ALBACH & STUEHLER, INC., Elizabeth, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Carl H. Stuehler, Morris M and Maxwell M. Albach, 210 Broad St., Elizabeth.

THE RIVERSIDE BRONZE & ALUMINUM CO., River and Lloyd Sts., New Haven, Conn., has been organized to manufacture bronze, brass, aluminum and other metal products. T. E. Hyde is president, and H. S. Brown, treasurer.

THE NORTHWESTERN RUBBER CO., Seattle, Wash., has been incorporated with a capital of $100,000, to manufacture rubber products of various kinds. The company is headed by C. E. Elliott, and is represented by Van Dyke & Thompson, 812 Lowman Bldg., Seattle.

THE SHULBERG CO., INC., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are L. and S. Shulberg, and I. Gettinger. The company is represented by Gettinger & Weiman, 63 Park Row, New York.

THE POLY CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of $70,000, to manufacture chemicals and chemical byproducts. The incorporators are F. Haber, L. Rothstein and V. Blancheri. The company is represented by Charles Firestone, 299 Broadway, New York.

THE STANDARD FOUNDRY PRODUCTS CO., 661 East Lafayette St., Detroit, Mich., has been incorporated with a capital of $15,000, to manufacture iron and other metal castings. The incorporators are Karl D. Stellwagon, Anthony J. Detlaff and Joseph F. Racine, 647 East Lafayette St., Detroit.

THE LYNCHBURG PAINT & COLOR CORP., Lynchburg, Va., has been incorporated with a capital of $25,000, to manufacture paints, varnish, colors, etc. A. T. Quick, Jr., is president, and H. B. Hughes, secretary, both of Lynchburg.

THE RICH STEEL PRODUCTS CO., Vernon, Cal., has been incorporated with a capital of $3,500,000, to manufacture iron and steel products. The incorporators are Richard L. North, L. L. Otis, H. F. Prince and S. M. Haskins. The company is represented by Gibson, Dunn & Crutcher, 1111 Merchants' National Bank Bldg., Los Angeles, Cal.

THE REX MCDILL CO., Haines City, Fla., has been incorporated with a capital of $200,000, to manufacture chemicals and chemical byproducts. Rex D. McDill is president and general manager, and Fred J. Hampton, secretary, both of Tampa, Fla.

THE BAINTSVILLE OIL & REFINING CO., Wilmington, Del., has been incorporated under state laws with a capital of $5,100,000, to manufacture petroleum products. The company is represented by the Corporation Service Co., Wilmington.

THE PENN LEATHER PRESERVING CO., Pittsburgh, Pa., has been incorporated with a capital of $10,000, to manufacture leather preservatives and kindred compounds. N. B. Trumbo, McKees Rocks, Pa., is treasurer.

THE CURTIS PROCESS REFINING CO., Indianapolis, Ind., has been incorporated with a capital of $100,000, to manufacture refined oil products. The incorporators are F. A. Curtis, C. B. Cox and B. W. Templeton, all of Indianapolis.

THE GOLD SEAL CO., Bloomfield, N. J., has been incorporated with a capital of $125,000, to manufacture fiber products and affiliated specialties. The incorporators are George M. Browning, Robert W. Nicholls and William P. Baerenrodt, 251 Spruce St., Bloomfield.

THE KLEAN-O PRODUCTS CORP., 1307 North Clark St., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture chemical compounds and preparations. The incorporators are N. M. Strebel, H. W. Bjernson and Sexton Bruce.

THE AMBER OIL CO., Bowling Green, Ky., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are J. E. Waldron, A. H. Malaney and B. J. White, all of Bowling Green.

THE WATER VALLEY FOUNDRY CO., Buffalo, N. Y., has been incorporated with a capital of $20,000, to manufacture iron and other metal castings. The incorporators are M. A. and C. A. Fries, and J. L. Babinger. The company is represented by Harding & Harding, attorneys, Buffalo.

THE UNITCO POTTERY CO., Trenton, N. J., has been incorporated with a capital of $125,000, to manufacture sanitary earthenware and other pottery products. The incorporators are John Morgan, William G. Amisson, Sr. and Jr., 77 Frazier St., Trenton.

THE CLINCH RIVER ZINC CO., Memphis, Tenn., has been incorporated with a capital of $500,000, to operate zinc properties and manufacture zinc products. The incorporators are John Cunningham, Arlington, Tenn.; and P. R. Cary and B. D. Bird, both of Memphis.

THE BRITE-LITE POLISH CO., Tulsa, Okla., has been incorporated with a capital of $25,000, to manufacture polishes and kindred products. The incorporators are P. G. Heffelfinger and S. S. Bassett, both of Tulsa.

THE SEARCHLIGHT PAINT SUPPLY CO., 5-7 Commerce St., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture paints, oils, etc. The incorporators are William H. and Charles I. Jamieson, and Bernard J. Flynn.

BRUCKNER, LIPPMAN & JACOBS, INC., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture leather products. The incorporators are M. Bruckner, I Lippman and D. S. Jacobs. The company is represented by Joseph Kohler, 280 Broadway, New York.

THE AMERICAN CONCRETE TILE & PRODUCTS CO., 426 New Amsterdam Bldg., Baltimore Md., has been incorporated with a capital of $250,000, to manufacture cement roofing tile and kindred products. The incorporators are John W. Ritter, John E. Springer and John T. Davis.

THE WINDSOR LOCKS PAPER MILLS CO., Windsor Locks, Conn., recently incorporated, has been organized with H. H. Turner as president; H. E. Platt, Jr., treasurer; and J. R. Kedley, secretary, Windsor Locks, to manufacture paper products.

THE RUBBER PROCESS CORP., Detroit, Mich., has been incorporated with a capital of $50,000, to manufacture rubber products under a special process. The incorporators are A Frank Bigger, Leo and Eugene Siegel, 1060 Fort St., W., Detroit.

THE OXAGINE CHEMICAL MFG. CO., Wilmington, Del., has been incorporated under state laws with a capital of $1,000,000, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Service Co., Wilmington.

THE ARISTO PRODUCTS CO., New York, N. Y., has been incorporated with a capital of 10,000, to manufacture polishes and kindred compound products. The incorporators are I. L. Hopkins, P. Berman and M. A. Karp. The company is represented by Goldstein & Phillips, 217 Broadway, New York.

THE ELIBI PRODUCTS CO., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are W. H. Haack, J. C. Williams and R. S. Kristeller. The company is represented by Watson, Kristeller & Swift, 68 William St., New York.

Manufacturers' Catalogs

THE HAMILTON COPPER & BRASS WORKS, Hamilton, O., has issued Bulletin 52 describing and illustrating Hamilton copper steam-jacketed kettles for the chemical and related industries. These kettles are furnished with or without agitators; one model is particularly designed for thick or lumpy materials. Capacities 25 to 250 gal. are carried in stock.

THE SULLIVAN MACHINERY CO., Chicago, Ill., has issued three new illustrated bulletins. Bull. 71-F is on the Sullivan Displacement Pump for Elevating Acid by Compressed Air; Bull. 70-W. on Sullivan Rotators and Bull. 71-G on the Sullivan Air Lift Pumping System, giving methods and apparatus.

THE CHICAGO PNEUMATIC TOOL CO., New York, has issued a special bulletin which should be of value to users of pneumatic tools, because it gives specifications which can be used as a reference when ordering tools. Bull 70, on vacuum pumps, which is the first of its kind to be issued by this company, contains information on dry vacuum pumps, steam, belt or motor driven.

THE CHAPMAN ENGINEERING CO. Mt. Vernon, O., has issued a booklet on Erecting and Operating Instructions. It contains detailed instructions for successfully operating a bituminous gas producer.

THE HAUSER-STANDER TANK CO., Cincinnati, O., announces a new publication entitled "Wooden Tanks for Every Purpose." The construction of wooden tanks for general use is shown, as well as specially constructed and irregular shaped tanks for special purposes. Especial attention is called to a study of the action of various chemicals upon different woods used for chemical tanks.

THE MINE SAFETY APPLIANCES CO., Pittsburgh, Pa., calls attention to Bulletin 72, on Burrell Gas Masks, for use in carbon monoxide and for all service.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 2, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN ENGINEERING COUNCIL will hold its next meeting in Washington, Jan. 5-6.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

PERKIN MEDAL will be presented to William M. Burton by the Society of Chemical Industry at its meeting Jan. 13 at the Chemists' Club, New York.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Jan. 6—American Chemical Society, regular meeting; Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

"Prohibiting" Chemical Warfare

THE accomplishments of the Disarmament Conference have been of an epoch-making character and the high principles that have guided its work have received universal acceptance and approval. It is, therefore, with no small measure of temerity that we raise our voice to question its recent stand on chemical warfare. As an expression of humane purpose and magnanimous intent the resolution may be worth while, but as a means of actually prohibiting the use of gas in warfare we are inclined to doubt its efficacy. Some way or other we cannot help but feel that it was a mistake to disregard the recommendations of the committee of experts and to accept the views of the non-technical advisers, even though they included officers high in the councils of the Army and Navy Departments.

It will be recalled that the committee of experts consisted of Professor EDGAR F. SMITH, chairman, and Brigadier-General AMOS A. FRIES for the United States, Colonel BARTHOLOMEW for Great Britain, Professors MOUREU and MAYER for France, Colonel PENTINALLI for Italy, and Major-General HARAGUCHI for Japan. This committee had presented a logical, convincing report supported by incontrovertible evidence from the late war. They proved that it was not feasible for the Conference to attempt to prohibit gas warfare, and that manufacture of poison gas as a military agency could not be controlled. On the other hand, the reports of those who opposed this form of warfare were noticeably weak, in our opinion, and inclined to deal in the sort of generalities that appeal to our broader sympathies, even though they do not always influence our better judgment. They state that chemical warfare is "a cruel, unfair and improper use of science," but for that matter so is all of warfare. Furthermore, it is quite contrary to the fact to claim that the use of gas inevitably results in its application to non-combatant as well as combatant. An unscrupulous enemy might so apply it, but there is no more reason why he must than there is that he should bomb a defenseless city with high explosive or sink an unprotected hospital ship with his torpedoes. The choice is his.

But let us turn to the resolution for a minute to find out, if we can, something of its real significance. It reads as follows:

> The use in war of asphyxiating, poisonous or other gases and all analogous liquids, materials or devices having been justly condemned by the general opinion of the civilized world and a prohibition of such use having been declared in treaties to which a majority of the civilized powers are parties;
>
> Now to the end that this prohibition shall be universally accepted as a part of international law binding alike the conscience and practice of nations, the signatory powers declare their assent to such prohibition, agree to be bound thereby between themselves and invite all other civilized nations to adhere thereto.

Is chemical warfare to be forgotten as a nightmare of the past or does this resolution mean, as one diplomat is quoted as saying, "that in the next war each of us promises to wait until the other fellow uses gas before we do?" The mere restating of an international law which has already failed to withstand the actual test of war can scarcely be regarded as a lasting solution of this problem. Under these circumstances preparation for chemical warfare must go on, for no nation can afford to be unprepared against a treacherous nation which may refuse to be governed by the law of nations. There are no penalties attached as was the case with the submarines, which, by the way, were limited as to use and not abolished. The only punishment awaiting the user of poison gases is the moral condemnation of other nations, and this, to be effective, depends upon the support given it by the public opinion of the world.

The attitude of the other powers toward the Conference resolution is a matter of considerable interest. Great Britain appeared somewhat skeptical of its efficacy. The French delegates seemed considerably more enthusiastic in according their approval to the resolution, while in the case of the Italians and Japanese the proposition was met with joyous acclaim. Apparently the sentiment against chemical warfare varies inversely with the size and development of a nation's organic chemical industry.

The importance of peace-time chemical plants for dyes and medicines is still evident. Governments bound by international agreement to prohibit gas warfare will continue to make gas masks and other defensive equipment, but they cannot, in good faith, erect and operate chemical arsenals for the production of poison gases. Should the world again be faced by a conscienceless enemy, the only safe preparedness lies in the organic chemical industry, with its plants and chemically trained personnel.

All Is Vanity And Vexation of Spirit

BY WHAT curious twist of the ego does a man who has achieved reputation and eminence in his chosen calling betray himself into attempting to speak with authority on other matters of which he knows little or nothing? What is it that apparently leads a man to believe that because his opinion would be accepted on a certain subject, his voice will be equally effective if lifted up in the wilderness of his ignorance? Recently we seem to have had an epidemic of this kind of public pronouncement by prominent men on topics quite outside their knowledge.

First, Mr. EDISON and Mr. FORD inspected the great nitrate plant at Muscle Shoals and we were informed that the former was so pleased with the place that "he would like to wander through it all night." We admit it is a fascinating plant, and we are only sorry that the process used at No. 1 was a failure. But Mr.

EDISON was more than fascinated, and we can take heart because he "offered several suggestions for making the process a success, but as the plant is not running they cannot be tried out now." This is truly unfortunate. Mr. EDISON should have visited the plant several years ago.

And after Mr. FORD had been to Muscle Shoals he delivered himself of a profound opinion on money and methods of financing which consist simply in "displacing gold as the basis of currency and substitute in its place the world's imperishable natural wealth." Thus we would put an end to war because "the cause of all wars is gold." He would substitute energy units for the precious metal and issue currency thereon—a sort of horsepower dollar.

But at the same time that Mr. FORD was condemning gold, Professor IRVING FISHER, economist of Yale University, was upsetting all our industrial calculations by holding out the possibility of Germany paying her reparations by means of synthetic gold. Addressing the London School of Economics, Professor FISHER is reported as saying that he has "been credibly informed that a German chemist has already succeeded in a laboratory in making synthetic gold out of baser metals by means of an electric vacuum furnace." Note the vacuum. Let the process become cheap enough and the Germans could "flood the world with chemically manufactured gold and so make it worthless." This should satisfy Mr. FORD.

We repeat the question with which we opened our discourse, and leave the reader to answer. When Mr. EDISON talks on electricity, Mr. FORD on automotive industry and Professor FISHER on economics we listen with rapt attention, but somehow when they respectively deliver sober opinions on nitrogen fixation, economics and synthetic gold, we grow restless and perhaps a bit disrespectful. We wish they wouldn't do it, because we like to hold them in the highest esteem.

Salaries for Government Professional Men

ON DECEMBER 15 the House of Representatives passed a bill (H.R. 8,928) for the classification of civilian positions in the government which establishes grades for the professional workers in the federal service. In order that uniformity of practice may prevail in the several technical bureaus and proper attention be given to salary scales of all, it is a distinct step forward to have this bill receive favorable action.

The salaries provided for beginners (college graduates) in professional work will be from $1,620 to $1,980. The next grade will be $2,100 to $2,640, and so on until finally the highest compensation recognized is for those in the chief professional grade, which "shall include all classes of positions in this service the duties of which are to act as the technical and administrative head of a major professional or scientific bureau," for which the compensation is to be $5,400 to $6,600 unless a higher rate is specifically authorized by law. No one will claim that these salaries are wholly adequate, especially in the higher grades. But apparently they represent a slight increase for the professional workers and as such should be welcomed.

The legislation is, however, seriously defective in two particulars. It provides that all vacant or new positions must be filled at the *minimum* rate of the appropriate grade. Thus apparently if a man is not qualified for $2,100 as an assistant chemist, the maximum which could be paid him would be $1,620. In other words an $1,800 man outside the service could not be recognized as such even though an $1,800 vacancy might exist; such vacancy would have to be filled by promotion. Also it would appear that the bill contemplates more or less automatic promotion for professional workers "not more than once a year." This places the professional workers as cogs in a mechanical personnel scheme of the most vicious sort. It applies the rule of seniority almost without regard to merit or efficiency.

Industries interested in chemical classification and compensation of professional workers will be glad to study and may profit by considering the proposed rates of compensation and the rather loose but significant classification of the positions. However, it is certainly to be hoped that they will not follow either a rigid scheme of salary fixing or any idea of automatic promotions. Either of such practices is vicious in the extreme when applied to scientific or professional workers.

Co-operation to Promote Our Foreign Trade in Chemicals

THE Bureau of Foreign and Domestic Commerce has made an unquestioned success of its effort in the commodity divisions already organized for the furtherance of foreign trade by investigation and report on domestic and foreign problems of production, distribution and marketing. One of the very first divisions contemplated last year, when this work was being planned by Secretary HOOVER and his assistants, was a division of chemicals. However, that division of the work has never been organized, largely if not wholly because the industries for which the service was designed showed a very obvious unwillingness to co-operate in the work. Apparently the difficulty arose from a confused idea in the minds of some prominent members of the heavy-chemicals industries that this work in promotion of export was interlocked with some statistical work regarding the domestic industries in the Bureau of the Census to which these industrial leaders found objection.

For the fiscal year beginning July 1, 1922, it is proposed in the national budget that additional commodity divisions be organized. Thus far there have been more than a dozen such divisions, including those on iron and steel, rubber goods, textiles, fuels, leather, etc. It is now proposed that divisions be added to deal with vegetable oils and breadstuffs, dyes and drugs, heavy chemicals, paints, varnishes and tanning materials, paper, non-ferrous metals, glass and earthern ware, petroleum and others not so directly of chemical interest. And the need for these is clear.

Stabilization of many chemically controlled industries demands that at least a small percentage of the products of these industries be exported. The federal government's effort to stimulate and stabilize such export business is, therefore, of great importance. It is to be hoped that the requested appropriations for the extension of the work will be granted.

It is even more to be hoped that the chemical industries will not again make the mistake of seeming to be unwilling to co-operate with the Department of Commerce. That department can do much good for the industries, and if co-operation on the proper basis is assured there is no likelihood of objectionable practice within the department. The organic chemical industries of the country recognize these facts. May the other branches of chemical business appreciate them also.

Soft Lead And Soft Soap

A SERIES of four articles by JEROME ALEXANDER, discussing the colloid state in metals and alloys, commences in this issue. It is of a nature which should and probably will interest many readers, both metallurgists and chemists, as the title attempts to indicate. Again, its perusal should build an excellent background for Dr. BANCROFT'S forthcoming lecture before the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers on "Colloid Chemistry and Metallurgy," even though it may be expected that these two gentlemen will view the subject in different perspective. Rather than infer the ultimate constitution of alloys from information gained when studying viscous colloids, BANCROFT would probably reverse the process, and argue from the "simple" alloy structure to the "complex" jelly.

The principles of colloid chemistry undoubtedly have intimate bearing upon that most practical problem of metallurgy: hardening. It has long been accepted that at high temperatures, carbon (the iron-hardener) is in solution or atomic dispersion in the hot solid metal, whereas after slow cooling it accumulates into visible crystals of carbide. Somewhere early in the range between these two extremes, which are both soft, occurs a certain arrangement of submicroscopic (and doubtless colloidal) particles of carbide which is associated with extreme hardness. Such facts as these led ALEXANDER, as early as 1908, to assume that maximum hardness in metal corresponds to "zones of maximum colloidality," where the system exhibits surface phenomena to the highest extent.

At that time steel was about the only metal which could be usefully hardened. In more recent years duralumin has been shown to be another such, and Dr. MERICA led fellow investigators in defining the conditions of its behavior, thus: "There is a certain size of particle of $CuAl_2$ [insoluble in the aluminum] for which the hardness of the material is a maximum." Dr. JEFFRIES later dubbed this condition a "critical dispersion." Recently he has given a highly useful view on the actual mechanism of hardening action in his paper on "Slip Interference Theory of the Hardening of Metals," appearing in these columns a few months ago —a contribution, by the way, which many chemists could read with advantage, despite its metalliferous title.

It may only be invidious to discuss priority in these ideas, and doubtless agreement could never be reached among colloid chemists and physical metallurgists, because of a fundamental difference in mental processes. The chemist fixes his attention upon surface forces, and without requiring any working model of their action, readily agrees with ALEXANDER that there is a certain fine subdivision of phases which possesses the maximum amount of internal energy and hence greatest hardness. The metallurgist requires a more, shall we say, mechanistic demonstration of the problem. He has been used to working with solid and relatively rigid masses of crystalline metal; he associates the idea of hardness with certain tests he has made on the metal; he observes certain microscopic changes to accompany permanent deformation; and naturally an explanation of hardness which appeals to him must use his terms and explain his facts. This Dr. JEFFRIES and Mr. ARCHER have done in a most skillful way.

Perhaps both are right!

Byproduct Coking For the Public

IN ONE SENSE we have been doing exactly the wrong thing with byproduct coke ovens, for most of those we have built have been located adjacent to blast furnaces. Of course the word "we" is used to represent society collectively. It may be asked how a better location for a plant can be found than next door to the largest consumer of the product involved. It is true the blast furnaces have been using 75 or 80 per cent of all the coke the country has been producing, but the coke produced represents only about 10 per cent of all the bituminous coal produced. Speaking for national economy, a great many of those who are consuming bituminous coal should be using byproduct coke.

Most of the byproduct ovens built have been located at blast furnaces because the steel industry had the capital and was willing to invest it. The record of 1921, with production of both pig iron and steel ingots at 37 or 38 per cent of the productive capacity, shows that the blast furnace is not a steady consumer of coke. Households and public utilities are much steadier consumers, and as a byproduct coking plant is one that involves a very heavy investment, it should be predicated on as steady an operation as can be compassed.

The wide variation in blast-furnace coke requirements from time to time has occasioned much less economic loss than would be the case if byproduct ovens were depended on solely at the time of maximum load. Speaking approximately, the coking capacity of the country is divided one-half beehive and one-half byproduct. Last July, when blast-furnace operations were at their minimum, coke production was aligned one-eighth beehive and seven-eighths byproduct, and thus in a measure the remaining beehive coke ovens of the country exist to carry the peak of the load.

It might be argued that the blast furnace and steel plant can provide itself with a full complement of byproduct coke ovens, and then sell to the public when its own requirements are light, as is so frequently the case. One difficulty is that rail freight rates are high even for very short coke hauls, while a greater difficulty is that the gas cannot be freighted at all. The byproduct coking plant located near a municipality can truck its coke and pipe its gas and count on a much steadier demand than is furnished by blast furnaces and steel mills.

It is established that the iron and steel industry can well afford to carry byproduct coke-oven investment even though the employment of the facilities is quite irregular. Much more, then, can the investment be carried when the arrangement is such that there is a relatively steady demand for the coke and gas. A recent transaction involving approximately 100,000 tons of byproduct coke indicated that the producer had a leeway of about a dollar a ton in underselling the actual cost of producing and transporting Connellsville coke. The computation was complicated, involving cost of coal and coal freights, value of byproducts, etc., but the net result was approximately as stated. The byproduct coke producer does not, however, retain the money, since nearly all of it goes to the railroad that transports the coke. If the ovens could be moved to the point of coke consumption for the life of the contract, this would be saved, as the assembly cost of the coal would not be increased. Thus it is advantageous to locate the plant so that there will be no freight on the coke. There is no milling-in-transit arrangement for coal and coke.

Seriums and Anta Toxines

To the Editor of Chemical & Metallurgical Engineering

SIR:—My friend ——, well, now, never mind what his name is. He is a little shy about seeing it in print, but I shall ask you to take it from me that he is a real chemist and would be one even in New Jersey, where they are tagging them. He has been receiving letters in reference to a chemical venture in Kansas City from the treasurer of the prospective concern, and on reading them they seemed so interesting to me that I begged him to let me offer at least one of them to you for publication. This reads:

> Dear Sir, I am writeing you at the suggestion of Mr. —— of ——. He tells me you are a practical Chemist, now at this time we are Organizing a large plant for Kans City Mo. we have enough Stock sold and promiced at the present time to put it over in a smaller way than we wanted to start with; but we are not tiard of well doing so are going to add some more to what we now have, we expect to Manufacture a full and compleet line of Chemicals and specilize in Seriums Anta Toxines, Glanular Extracts, and in fact other lines not mentioned, we thought perhaps you would like to connect yourself with a concern like this, in a Financial way at the present time, and in the future you wished to employ yourself in this capasity in this part of the U S, the writer believes it would be a fine thing for you to associate yourself with this young Factory before the present issue of stock is raised in price above par we are issueing Stock at par value of $10.00 per share would like to hear from you if interested will mail you a compleet prospectus of the whole situation. Respt Yours J. D. HENDERSON, Treas.

There is another one from the same erudite gentleman setting forth the advantage of getting in on the ground floor so that my friend may participate in "the groth" of the company. It tells him that, he being a chemist, "there is no use to dwell on the profeit end of the business" and "hense" he will understand it.

The officers of the company are respectively Messrs. Thompson, president; Henson, secretary, and Henderson, treasurer—all sons, you observe. The correspondence makes me want to urge old Mr. Thomp, Mr. Hen and Mr. Hender to send the boys to school for a while before they begin to produce their "seriums."

There is nothing to hinder these promising gentlemen from engaging in pharmaceutical industry, but I can't help wondering how the scholarly gentlemen of the Kansas City Section of the A.C.S. will greet their new colleagues. MARTIN SEYT.

Various Methods for Hardening High-Speed Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with interest Mr. d'Arcambal's paper on "Various Methods for Hardening High-Speed Steel," which is published in the Dec. 21, 1921, issue of CHEMICAL & METALLURGICAL ENGINEERING. Mr. d'Arcambal, in speaking of blisters and pitting of high-grade steel when heated in barium chloride, lays this trouble to the graphite crucible.

Several years ago I had occasion to experiment with barium chloride as a heating bath for high-speed steel. The furnace first used was an oil-fired crucible furnace, the container was a graphite crucible. The work hardened from this bath when new, showed no sign of blister or pitting, but after a day or so of use the steel would blister. In form the appearance of these blisters was that of oyster shells. Examination at that time led us to believe that the trouble came about by the surface of the steel flowing from one spot and building up at another spot. In other words, pits and blisters existed together. It was found that this trouble could be eliminated by a renewal of the barium chloride until that in turn became unfit for use. It was also found that an accumulation of molten metal took place at the bottom of the crucible. This was found accidentally by dropping the tool being hardened to the bottom and on its removal a considerable quantity of this metal had adhered to it, rendering it quite useless. At first it was thought the tongs and poker used in holding the work had melted sufficiently to cause this accumulation. Some of this metal was saved and although never analyzed, it was undoubtedly due mainly to successive drippings from the high-speed tool.

Brearley, in his "Heat-Treatment of Tool Steel," shows several pictures relating to the above findings. He also analyzed the metal found at the bottom of the crucible as follows: Carbon 2.56 per cent, manganese nil, chromium 1.13, tungsten 8.48.

It is a question whether this action of barium chloride on steel is in any way related to the action of borax in carburizing and adding of new metal, as claimed under British patent 125,666, by Samuel Whyte, May 1, 1919.

Hardening of high-speed steel in barium chloride contained in a firebrick crucible did not cause the trouble referred to in the graphite crucible.

Hydrochloric Acid as an Etching Reagent

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your journal of Nov. 23 we noted an article on the use of concentrated hydrochloric acid as an etching reagent for nickel, written by Henry S. Rawdon and Marjorie C. Lorentz. This proved doubly interesting to us, as we had accidentally discovered the value of hydrochloric acid in this connection.

A short time ago, while using nickel shot as a reducing agent in a rough analysis of a solution of tin in concentrated hydrochloric acid, we noted that very shortly after boiling commenced, the nickel appeared to be etched. Subsequently, a specimen of the same nickel was properly prepared and polished, and the etching value of boiling concentrated hydrochloric acid tried. The results were highly satisfactory. In from 2 to 5 minutes etching was completed, the crystal being as clearly defined and contrasted as those shown in Fig. 1*b*, of the above article, which represents a section of a sample which had had 1 hour's etching with cold concentrated acid.

We have since on different occasions used boiling concentrated hydrochloric as a metallographic etching reagent for nickel, and uniformly excellent results have been obtained. W. G. ROBERTSON,

Faculty of Applied Science, University of Toronto. A. H. MELLISH.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Dec. 17, 1921.

PROBABLY the chief topics for discussion during the past month have been the santonine and gas mantle cases, which have just been dealt with by Cyril Atkinson, K.C., the referee appointed under the safeguarding of industries act. While British chemical industry as a whole has been deeply concerned as to the outcome of these test cases and the technical journals have given considerable prominence to the very conflicting evidence presented by the "experts," the daily press, including the *Times*, has scarcely referred to what are certainly far-reaching decisions of great importance to industry.

When Is a Chemical Not a Chemical?

In some respect the chemical evidence and the judicial mind may be said to have been trying to answer conundrums rather than taking a broad common sense view. Santonine is a medicinal chemical extracted from flowers grown in south Russia, and its supply is at present under the control of German and Russian interests, which have raised the price by about 800 per cent over the pre-war level. The raw material could also be collected within the British Empire and santonine is apparently a crystalline substance of definite composition, which might conceivably be synthesized and thus ultimately come under the act as a synthetic organic chemical. Yet on the balance of the evidence it has been held that it is not a "fine" chemical, and so the game goes on. The primary purpose of the act is to safeguard industries actually carried on or likely to be carried on in this country, and in excluding santonine from its operation the general opinion seems to be that the decision interprets the spirit of the act and the intentions of the legislature. Next week it is the turn of calcium carbide on the motion of the British Cellulose & Chemical Manufacturing Co., of airplane dope fame, which installed at the request of the government a 30,000-ton carbide plant during the war, and although this manufacture may not be economically sound, it is thought to be a key industry requiring protection. If, on the evidence, carbide is deemed to be an organic chemical, an import duty of 33 per cent would be imposed, and speculation is rife as to what would then happen in the case of putative organic compounds such as the carbonates, carbon bisulphide, solid carbon dioxide, dissolved acetylene and kindred substances containing carbon. The third case to be heard will be that of cream of tartar, and it is confidently predicted that by then our legal luminaries will be in hospital suffering from brain fever.

Rare Earths in Gas Mantles to Pay Duty

The gas mantle case turned on the conundrum, "When is a compound not a compound?" some of the experts suggesting that a chemical compound was necessarily referred to in the act and that a mixture was not included. The common sense view prevailed in this case and the cerium and thorium contents of the mantle are now subject to duty, but not the gas mantle as a whole. Probably further protection under the dumping clauses will now be sought by the manufacturers, as unless the whole mantle is taxed, the amount of the duty imposed would be insufficient to enable continental competition to be met successfully. Both in the santonine and gas mantle cases the awards have not yet been signed and the Board of Trade appears to be unjustifiably endeavoring to have the decisions modified —probably without success.

Sir Arthur Duckham Announces Probable Solution of Peat-Drying Problem

In stating last month that one or two important inventions were on the point of fruition, the new drier and evaporators for the treatment of peat developed by Peco, Ltd., which has carried on the work of Wet Carbonising, Ltd., and Testrup, were among others in your correspondent's mind. It is understood that 1 ton of fuel in these apparatus will be capable of removing about 20 tons of moisture from peat, and an experimental plant is now being erected with a capacity of about 40 tons a day. Sir Arthur Duckham is at the head of Peco, Ltd., and is very sanguine as to the future of the invention, which should be of great importance to Canada, Italy and Great Britain among others. Plauson's colloid mill, regarding which propaganda has recently been made, is perhaps in a different category, because it has been very diffcult to obtain trustworthy information or to get down to business. Briefly, Plauson claims to grind in water as a disperse medium rubber and many other materials to a fineness of between 1 μ and 10 $\mu\mu$—i.e., 0.001 mm. and 0.00001 mm.—and that in this "colloidal" condition with or without the addition of certain substances acting as protective colloids an entirely new field is opened in soap manufacture, fat hardening, colloidal wood, graphite, etc. Plauson and his financial agent in London have protected the invention with a cloud of patents, but so far no one seems to have seen the mill in satisfactory operation or has learned anything regarding its efficiency, output or the power required to drive it.

General Notes

There is quite a vogue in rustless irons and steels at the moment and in addition to Vickers' and Krupp's steels referred to in my last month's notes, the rustless iron made by J. J. Saville & Co., Ltd., is worthy of notice. It differs from the others in not requiring hardening and in that it is ductile with a tensile strength of 40 tons and an elongation of 25 per cent with a reduction of area of 60 per cent. These properties enable it to be pressed, spun, stamped or cold-worked into the most intricate shapes without requiring subsequent heat-treatment, and in the soft condition, when polished, will not tarnish or rust and will probably also find a limited application in the chemical industry. Very little progress has been made in electrolytic iron and the new material seems to be a good substitute. West's paper on the Claude process [see p. 58 of this issue] has failed to draw any reply or information from the Brunner Mond group and meanwhile there is a tendency to reconsider the merits of the Häusser explosion process for direct production of nitric acid from coke-oven gas, which would be a very useful adjunct to ammonia synthesis, particularly as the oxygen obtained as a byproduct could be used to increase the yield from the explosion process. The recent cinematograph evening organized by the Society of Chemical Industry was the first of its kind in this country and it is generally thought that the use of motion pictures so prevalent in America will be extended and that films shown in the future will be of a standard more comparable with those usual in America.

Colloidal State in Metals and Alloys. I—Molten Metal

Just Prior to Solidification, Metal and Glass Show Many Similarities—Pure Molten Metals Are Doubtless Isocolloids—Ultramicroscopic Researches on Glass Are Quoted to Indicate Expected Results When Such Studies May Be Extended to Metal

BY JEROME ALEXANDER*

THE object of this paper[1] is to show that many of the important phenomena of metals and alloys are due to the facts that at a certain stage of their existence they or some of their constituents are in a colloidal state of subdivision, and that notwithstanding the generally brief duration of this stage and the powerful crystallization tendency of metals, a portion of the metal or alloy tends to remain in the colloidal state and exert a powerful influence upon the physical properties of the final solid magma. Incidentally it will become evident that the so-called amorphous phase in pure metals is an isocolloid, consisting of colloidal groups of metal molecules which may be dispersed in still more finely subdivided metal; that these colloidal particles are not truly amorphous, but may consist in part, if not entirely, of ultramicroscopic crystals; and that the expressions "amorphous phase" and "amorphous theory" might with justice be replaced by the expressions "colloidal phase" and "colloidal theory."

Nature of Colloidal Particles

To avoid misunderstanding, allow me to recall that any substance is in colloidal state when the constituent particles consist of molecular or atomic groups, whose size varies approximately from about 100 $\mu\mu$ down to about 1 $\mu\mu$—that is, from just below the limit of microscopic resolvability down to the dimensions commonly ascribed to the larger molecules. It should be particularly noted that colloidality involves no assumption as to the shape, internal structure or orientation of the colloidal particles, size alone being the critical factor. A colloidal system may therefore contain crystalline groups, or amorphous groups (non-crystalline, random or haphazard clusters), or a mixture of the two. Thus the recent observations of Scheerer[2] with the X-ray spectroscope show that in certain gold and silver hydrosols the metal particles, including even those below the limit of ultramicroscopic visibility, consist of regularly oriented molecular groups—i.e., of tiny crystals, which show the same space lattice as macroscopic gold crystals. On the other hand, old specimens of silicic acid and stannic acid gels exhibit well-marked interference figures in addition to the characteristics of amorphous substances, and probably represent substances which are on the verge of crystallizing. Typical organic colloids, such as albumen, gelatin, casein, cellulose or starch appear to be truly amorphous.

Besides illustrating the point that a colloidal system may consist of crystalline or of non-crystalline groups, or of a mixture of the two, the results are of especial interest as showing the slow transformation, in the case of the silicic acid and stannic acid gels, of irregularly oriented into regularly oriented or crystalline groups, which indicates that the colloidal may be precursor of the crystalline condition.

Isocolloids

All colloids consist of at least two phases—the subdivided substance, or "dispersed phase," and the substance into which this is subdivided, the "dispersion medium." It should be particularly remembered that it is not even necessary that there be any chemical difference between the dispersed phase and the dispersion medium. For example, there is here given[3] in tabular form (Table I) a list of eight different "isocolloids" of water, where water forms both the phases.

TABLE I. WATER ISOCOLLOIDS

	Dispersion Medium	Dispersed Phase	Example
(1)	Solid ice....	Water vapor bubbles.....	Milk ice—turbid or milky white ice produced in refrigerating machines.
(2)	Solid ice....	Liquid droplets of colloidal size.....	G. Quincke (Drude's *Ann. Phys.*, vol. 18, p. 11, (1905), regards this as the usual structure of solid, "amorphous" ice.
(3)	Solid ice....	Solid ice in a colloidal degree of dispersion .	For proof of the existence of such systems, see G. Tammann, *Z. phys. Chem.*, vol. 69, p. 569 (1910); *Z. anorg. Chem.*, vol. 63, p. 283 (1909). According to Quincke (1) and (2) may be converted into (3) by reduction of temperature.
(4)	Fluid water	Water vapor bubbles of colloidal dimensions.....	Water, like other chemically homogeneous fluids near their critical vaporization temperature, shows turbidity, opalescence, varying density, etc.
(5)	Fluid water	Fluid water droplets of colloidal dimensions.....	Ordinary water is supposed to consist of a mixture of associated group (polyhydrol) and unassociated groups. See H. Schade, *Kol. Zeit*, vol. 7, p. 26 (1910) *Trans.*, Faraday Soc., vol. 6, pp. 71-129 (1910).
(6)	Fluid water	Colloidally dispersed ice....	This dispersion is unstable and exists only as a transition form. "Snow-water" is a similar coarser dispersion. See P. P. von Weimarn and Wo. Ostwald, *Koll. Zeit.*, vol. 6, p. 181 (1910). Colloidal ice is readily produced in chloroform or ether (von Weimarn; *loc. cit.*) or in ice cream. (J. Alexander, *Koll. Zeit.*, vol. 4, p. 106 (1909).
(7)	Water vapor	Colloidally dispersed water droplets.....	Fog, mist, clouds and (when coagulated) rain.
8)	Water vapor	Colloidally dispersed ice....	Fine snow or frozen fog, which in the upper atmosphere frequently produced a halo around the moon.

In addition to the ordinary ice referred to in Table I, there have been proved to exist at least four other kinds of ice, each heavier than water and stable only under the very high pressures at which they are formed.[4] Since cooling and contracting metals exert a powerful

---

The present series of papers was written mainly in the fall of 1919. Reduced to about half their original form, they were read before the Columbus meeting of the American Institute of Mining and Metallurgical Engineers, October, 1920, and will so appear in vol. 64 of its *Proceedings*. They are now given in full, together with some recent additions which are indicated by enclosure within square brackets [ ].

pressure upon their interior molecules, the question arises as to what extent this may influence their crystalline grouping. The fact that under uniform conditions one kind of ice formed in glass bulbs, whereas another variety formed in steel bulbs, seems to me to throw some light upon the effect of impurities in metals, for glass is slightly soluble in water at high pressure.[5] This relation is borne out by the fact that the presence of a few splinters of glass in the steel bulb, caused the appearance of ice *V*, the glass bulb variety. Bridgman's experiments also show that at 20,000 atmospheres pressure (about 300,000 lb. per sq.in.) paraffin and rubber actually become harder than is steel at the same pressure; further, that the expansive force exerted when water freezes into ordinary ice is about 30,000 lb. per sq.in. Water near the boiling point may be frozen by the application of a pressure of 20,000 kg. per sq.cm. As molecular forces are extremely powerful, we need not be surprised to find marked changes in the physical properties of metals to result from their application; and it is doubtful whether metal in the interior, especially of large masses, possesses the same properties as that on or near the surface, which alone is open to inspection.

Allotropy of Elements

Isocolloids may consist of a single element, in which case the dispersed and the dispersing phases are usually regarded as different allotropic forms of the element in question. Wo. Ostwald has proposed the term "allocolloids" for such systems, of which sulphur, selenium and phosphorus are typical examples. The relation to alpha, beta and gamma iron will at once occur to metallographists.

In describing the theory of dynamic allotropy W. E. S. Turner[6] says: "The fact that molecules of different kinds can co-exist in any liquid, the proportion of each depending on the temperature and other factors, has paved the way for a new view of allotropic modifications, according to which both forms can be present in a state of equilibrium. This theory has arisen more particularly as a result of the study of liquid sulphur, the abnormal behavior of which has been demonstrated to be due to a mixture of a mobile, yellow liquid called $S\lambda$, which predominates in amount, and a viscous brown liquid $S\mu$, the proportion of which increases with rise of temperature and attains a proportion of 40 per cent at the boiling point, 455 deg. The two forms are further distinguished and rendered separable, and therefore capable of determination, by the fact that $S\lambda$ is soluble, while $S\mu$ is insoluble in carbon bisulphide; indeed, corresponds in the quasi-solid form to the well-known amorphous sulphur. Certain reagents have the effect of stimulating the rate at which the equilibrium between the two forms is attained at a given temperature, other reagents retard the rate. Ammonia is such a stimulant, sulphur dioxide a retarder,[7] and by the addition of the latter, the mixture can be cooled and afterward analyzed without the equilibrium set up at the higher temperature being disturbed. Sudden cooling by plunging into cold water will also retard the change and preserve the equilibrium proportions."

By pouring a thin stream of liquid sulphur heated to 400 deg. into liquid air, von Weimarn[8] obtained a perfectly transparent and exceedingly elastic sulphur. In this case the extreme speed of the chilling with the accompanying rapid increase in viscosity inhibits both the allotropic molecular rearrangement and also the colloidal aggregation, the resulting allocolloid being a very finely dispersed sulphur sulphogel or solid sulphosol. Of interest also as showing the influence of surface conditions is the fact that sulphur crystallizes from hot oil of turpentine in the form of monoclinic prismatic crystals (sp.gr. 1.98), which are unstable and transform into octahedral rhombic crystals (sp.gr. 2.05) with the evolution of heat, the transformation being facilitated by scratching or vibration, or by immersion in CS_2 in which the latter form is soluble, and from solutions of which it is deposited on slow evaporation of the solvent.

Phosphorus shows a variety of allotropic forms (or mixtures of a few); and from the evidence discussed by P. W. Bridgman,[9] it seems obvious that ordinary red phosphorus consists of one allotropic form dispersed in another, the relative percentages depending upon the conditions of formation. In this paper Bridgman also describes a new black form of phosphorus (produced by pressure of 11,000 to 12,000 kg. per sq.cm. at 200 deg.), which is a fair conductor of electricity and has a sp.gr. of 2.691. White phosphorus has a sp.gr. of 1.83, red phosphorus a sp.gr. of 2.05 to 2.34 depending upon the method of its preparation; and both are perfect insulators. Thus, heating under high pressure results in an aggregation of some kind and gives phosphorus conductivity, a true metallic characteristic. In metals, a similar aggregation seems to occur because of the enormous cohesion or molecular attractive forces of the metal molecules themselves—a property made use of in shrinking on collars and the like and even in straightening the bulging walls of buildings by the shrinking of heated iron rods.

Mechanism of Solidification

When a metal is heated to fusion, the thermal agitation of its molecules is sufficient to overbalance, at least to some extent, the mutual attraction of its molecules; but this does not mean that the strong aggregation tendency of its molecules is without effect. On the contrary, in the state of kinetic equilibrium which exists, there must be a certain number of molecular groups, whose size and number tend to increase as the solidification point is approached—that is, as the thermal agitation diminishes. The higher the temperature to which the metal is heated and the quicker it traverses the zone of intense thermal agitation to the comparative quiet of solidification the smaller and more numerous will be the molecular groups. The general tendency seems to be for atoms or simple molecules to form crystals, whereas complicated molecules—especially those with several foci of attraction, like gelatine—tend to remain in random or colloidal clusters. Although Traube's experiments[10] indicate that liquid zinc, cadmium and mercury are monatomic, it is probable that investigation will show that all metals near their freezing points, and especially metals of high melting points, exhibit molecular association or else allotropism.

It would appear then that just prior to solidification and crystallization all pure metals are isocolloids—that

[5] The indications are that in volcanic depths, where high pressures and high temperatures exist, water and silicates exist as a jelly-like solid, which explodes into colloidal fragments upon sudden release, as at the eruption of Mt. Pelée at Martinique.

[6] "Molecular Association," p. 92. Longmans, Green & Co., 1915.

[7] Note the analogy to the effect of Mn in steel.

[8] *Koll. Zeit.*, vol. 6, p. 250 (1910).

[9] *J. Am. Chem. Soc.*, vol. 36, pp. 1344-1363 (1914).

[10] *Ber.*, vol. 31, p. 1562 (1898). W. E. S. Turner, citation (6), p. 53.

is, they consist of colloidal sized groups of metal molecules distributed in a more completely dispersed magma. But the dense concentration and proximity of their molecules, their powerful molecular attractive forces (their cohesion, to which they owe their strength and strong crystallization tendency) act so rapidly that, as a general rule, the major portion of the metal forms macroscopic or microscopic crystals, which are embedded in an intercrystalline network consisting mainly of colloidally dispersed metal having different physical properties from the crystals, of whose creation it constitutes a remaining vestige. While a fluid metal may contain a percentage of isolated molecules, it does not seem possible that many of these remain in the solidified metal, which consists mainly of macro- and microcrystals, and of oriented and unoriented groups of colloidal dimensions. Thus not even the most rapid chilling prevents non-magnetic γ iron from becoming magnetic, although at the temperature of transformation the metal is no longer fluid.

Effect of Grain Size

The more rapidly the fused metal is chilled the less opportunity there is for the growth of crystals beyond the colloidal stage—it is well known that quick cooling yields fine structure. The effect of quick chilling on the hardness and specific gravity of metals is illustrated by the following results, kindly worked out by W. A. Cowan of the National Lead Co.'s research laboratory. The chill castings were made in a water-jacketed cylindrical mold and measured 2 in. in diameter by 1 in. high. The slowly cooled specimens were of the same size and shape, but were cast in a hot mold, taking 12 minutes to solidify after casting from a moderate temperature. Small vertical sections, weighing about 20 g., were cut radially from the ingots, and the specific gravity of these was determined by immersion in distilled water, with weighings before and after. Before making the hardness tests, both sides of the ingots were machined flat, $\frac{1}{16}$ in. being removed from the bottom for testing surfaces. The results follow:

	Sp.Gr.	Brinell Hardness Numbers
Straits tin, chill cast	7.309	8.8
Straits tin, slowly cooled	7.301	7.7
Corroding lead, chill cast	11.367	5.2
Corroding lead, slowly cooled	11.354	4.4

As the differences between the melting and chilling temperatures in these experiments is, for metals, rather narrow, further tests are being made using liquid air as a chilling medium.

The results of quick chilling are analogous to those of cold hammering, which shatters the large grains and increases the percentage of colloidal metal present. Thus Zay Jeffries[11] reports the following results:

	Brinell Hardness Numbers
Cast tin, large grain	9.12
Cold-hammered tin	11.32
Cast lead, large grain	5.44
Cold-hammered lead	6.54

Much regarding the minute structure of metals may be determined by metallography, which involves the microscopic examination of suitably polished and etched metallic surfaces. Metallography has been most fruitful of results, and much of our present knowledge of metals and alloys has been attained with its aid, particularly knowledge of the crystalline phase or "grain." Of the so-called amorphous or colloidal phase, however, metallography can tell us but little outside of its occurrence and distribution. Owing to the great opacity of solid metals, it has thus far been impossible to subject the colloidal phase to successful ultramicroscopic examination, and such examinations of thin films along the lines laid out by Beilby present difficulties and cannot apply to the mass, although they may be of interest.

Similarities Between Hot Glass and Hot Metal

But glass may be readily examined ultramicroscopically, and a consideration of the phenomena observed in glasses will serve for the present to give some insight into what occurs in metals and alloys.[12]

Among glass technologists a molten batch of glass is termed "metal," a term remarkably well chosen, for, strange as it may appear, there are numerous analogies between glasses and most metals. Both are produced or fused at high temperatures, and as they issue from the furnaces are, for the most part, heavy viscous liquids[13] prone to set and crystallize. Both exhibit the phenomena of supercooling to a marked degree if quickly chilled. Both may be cast, molded, pressed, drawn and annealed or tempered—they are in fact thermoplastic and their physical properties are largely dependent upon their thermal and mechanical histories. There are, of course, many enormous differences between glasses and metals, and very marked differences exist even in their analogous properties. Thus with metals the crystallization tendency is powerful and quick acting, whereas with glasses the composition is generally chosen so as to prevent crystallization under operating conditions, some of the constituents of glass apparently serving as protectors or inhibitors of crystallization toward the others. Furthermore, metals tend to cool much more rapidly than glasses because of their greater thermal conductivity; but their rapid crystallization usually outstrips their chilling, notwithstanding the fact that the latter is often facilitated by quenching.

Behavior of Supercooled Melts

As Tammann has shown,[14] there are three main factors which control the behavior of supercooled melts: (1) The specific crystallization capacity (which is measured by the number of centers of crystallization formed in a unit mass in a unit time); (2) the speed of crystallization; (3) the variation in viscosity. In the case of the various mixtures of fused silicates composing molten glasses, the viscosity increases so rapidly upon cooling that the crystallization forces are unable to establish themselves before the melt becomes too rigid to permit molecular orientation. The result is the amorphous, or colloidal, mass we call glass. In very quickly cooled glass—i.e., Prince Rupert bubbles—the internal strains are so great that the glass is actually explosive; and in the ordinary process of manufacture glass has to be annealed to render it less brittle. This is accomplished by cooling the glass very slowly, keeping it at a low heat for a long time so that there may be a partial adjustment of the aggregation tendencies of its particles. Gelatin jellies act similarly, but, because of their softness, anneal spontaneously at room tempera-

ture.[15] Thus F. Stoffel[16] has shown that quickly cooled gelatin jellies permit the more rapid diffusion of electrolytes than slowly cooled jellies; but the difference equalizes itself after several days. Incidentally this shows the higher dispersion of the particles in the quickly cooled jelly and the greater total area of diffusion paths.

If the composition or heat-treatment of the glass is such that crystallization occurs, we call the phenomenon devitrification—the glass becomes cloudy or opaque. The inherent tendency toward crystallization exists even in clear glasses, and may be realized after a very long lapse of time. [The composition of opaque glasses is so chosen that under usual conditions a turbidity is produced, a fine precipitate which renders the glass opaque. Recently James Gillinder, of Port Jervis, N. Y., was kind enough to make for me some Prince Rupert drops from a batch of opal glass. The exterior rind of the drops was clear or showed a faint turbidity, whereas the interior, which was of course more slowly cooled, was milky and opaque. At the surface the chilling was from about 1,200 deg. down to 15 or 20 deg.] Thus ancient Egyptian and Roman glasses are frequently found to be devitrified. On the other hand, although old leaden roofs consist of metal showing coarse crystals, ancient iron shows practically the same structure as modern iron. We must remember that iron as a rule consists mainly of the crystalline phase, which is stable, not of the colloidal phase, which is metastable and can undergo slow hysteresis; besides, iron does not undergo annealing at ordinary temperatures.

Gold Ruby Glass

The work of Zsigmondy, on gold ruby glass,[17] has given us an understanding of what happens when a metal is dispersed in glass. When gold is added to a glass melt (usually 1 part of gold chloride to from 3,000 to 10,000 glass), it dissolves, and the molten glass is colorless and upon slow cooling may become red or remain colorless, depending upon the nature of the batch. If quickly cooled to a set, all grades of gold ruby glass remain colorless. Upon reheating colorless ruby glass to the softening point, a portion of the dissolved or molecularly dispersed gold separates out upon nuclei or crystallization centers already formed in the previously chilled mass, and the glass usually develops its normal red color. Spoiled batches, upon reheating, generally yield a blue or violet shade, but may yield an unsatisfactory red. Reproduced in Table II are the ultramicroscopic observations of Zsigmondy made upon good and upon spoiled ruby glass, using bright sunlight and a homogeneous immersion objective. Both specimens had been slowly cooled and then reheated more quickly than they had previously been chilled; they were heated so that at one end they began to melt (hot end), whereas at the other end they remained cold (cold end).

TABLE II.

	Color Red Decreasing ↓	Good Ruby Glass	Color Decreasing ↓	Spoiled Ruby Glass
Hot End				
a		Color intense red. Numerous green ultramicrons, very close together, their brightness diminishing.		Color blue. Ultramicrons fewer, copper-red, further apart.
b				Color violet. Ultramicrons yellow.
b'				
c		Homogeneous green light cone		Color bright red. Ultramicrons green.
d		Colorless and homogeneous.		Colorless. Few faint specks visible.
Cold End				

That with these particular specimens no new crystallization nuclei were formed upon reheating is evident from the fact that the average distance between the ultramicrons was the same in the intensely heated portions as in the less heated portions of the glass. "Colorless, slowly cooled gold ruby glass contains one part of its gold, therefore, in supersaturated solution, and the remainder in the form of nuclei so small that they affect the homogeneity of the glass only slightly or not at all. With batches of different composition, the temperature for the spontaneous formation of nuclei is so much higher that such glass colors up red on slow cooling."

Applying these principles to technical practice, Zsigmondy was able to explain certain heretofore incomprehensible observations. Thus, "The rim of a piece of pressed ruby glass remained colorless, while the middle became red. In the press the rim was more quickly cooled than the middle, and by subsequent heating was heated more quickly and to a higher temperature. Investigation showed that the rim contained a much lesser number but considerably larger green gold particles than the rest of the glass. The rim of the glass had very quickly passed through the optimum temperature for the formation of nuclei, so that only few were formed; subsequent heating to a higher temperature, therefore, led to a speedy growth of these nuclei into particles of 110 to 145 $\mu\mu$. The middle section of the glass had time enough to form a large number of nuclei, which, being less strongly heated, grew more slowly. In spoiled ruby glass the formation as well as the growth of nuclei is disturbed; fewer nuclei are formed and these grow more slowly than in good ruby glass."

Devitrification of Glass

Zsigmondy emphasizes the fact that the coloring of ruby glass should not be confounded with ordinary devitrification. "The difference between the two is that in the formation of ruby glass several milliards of nuclei exist and grow in a cubic millimeter, and that the hypothetical little crystals, of whose form and structure we know nothing, are so small that their presence changes only the visible appearance and not the working properties of the glass; whereas, in the case of devitrification, relatively few nuclei are present and lead to the formation of quite large crystals, which prevent the usual working up of the glass."

This difference is clearly seen on considering the facts brought out by N. L. Bowen in a recent paper[18] on the devitrification of glass. While many silicates may be cooled quite slowly without crystallizing, $MgSiO_3$, Al_2SiO_5 and $CaSiO_3$ crystallize unless quickly chilled, a condition difficult of realization because molten silicates combine high thermal capacity with low thermal conductivity. The composition of the batch must be chosen to prevent supersaturation with any component at any temperature at which the glass is to be subsequently maintained. If devitrification occurs when the glass is cooled preparatory to working (or prior to the final stirring in the case of optical glass), the crystals formed are usually large. When the glass is cooled from the plastic to the rigid state, as during

[15] So do soft metals; lead and tin, for example.

[16] See H. Bechhold, "Colloids in Biology and Medicine," p. 52, translated by J. G. M. Bullowa. (D. Van Nostrand Co., 1919.)

[17] "Colloids and the Ultramicroscope," (translation by J. Alexander). John Wiley & Sons Co., 1909.

blowing, drawing, casting and particularly when optical glass is being cooled in the melting pots, devitrification may occur through the separation of spherulites or minute crystals uniformly disseminated throughout the glass, making it opalescent. Microscopically these crystals were found to be trydymite and cristobalite in most cases investigated. Particularly interesting is the fact that their formation is facilitated by "mineralizers" such as SO_3 or Cl; arsenic acts similarly if in excess, and fluorine may do so. This reminds one of a "salting out" action; the opposite or protective action of constituents in a melt is illustrated by the facts brought out in a paper[19] by H. F. Bellamy on gold ruby glass. His results show that SnO_2 acts as a powerful protector or stabilizer, deepening the color of the glass to such an extent when added in optimum proportions that the the percentage of gold present has to be diminished.

The tin also keeps the color uniform over a range of reheating temperatures and prevents the development of light blue, purple or rose colors (which are indicative of coagulation or undue aggregation).

We have here a typical instance of protection in the colloidal sense, which is quite in line with the work of Zsigmondy,[20] who showed that the purple of Cassius (an ammonia-soluble deep red precipitate obtained by mixing solutions of chloride of gold and stannous chloride) is simply colloidal gold stabilized by colloidal stannic acid. Berzelius regarded the purple of Cassius as a chemical combination of tin sesquioxide and purplish oxide of gold, and Gay-Lussac, Debray, Müller and others contributed to the extensive literature concerning it. Zsigmondy settled the moot question, for he actually synthesized the purple of Cassius by mixing together the hydrosols of gold and stannic acid, thus proving it to be an adsorption compound of the two.

(Part II, dealing with Crystallization, will appear in a subsequent issue.)

The Claude Ammonia Process

AT A joint meeting of the Chemical Engineering Group of the Society of Chemical Industry and the Institution of Mechanical Engineers recently, J. H. West read a paper on the Claude synthetic ammonia process and plant, published in abstract in the Dec. 9, 1921, issue of *Iron and Coal Trades Review*. The author is associated with the Cumberland Coal Power & Chemical Co., which is erecting works at Workington to operate the process. The company has acquired three collieries in Cumberland, whose coke ovens are capable of making 3,000 tons of coke per day. With the view of obtaining a supply of hydrogen immediately and under the best conditions, a controlling interest has been acquired in the Tysse Water Power Co., in Norway, which has a plant of a capacity of 145,000 electrical hp. The cost of power for the production of hydrogen is about £1 per hp.-yr., or 0.04d. per kw.-hr. This acquisition also gives the company rights over the carbide factories at Odda, and with these means for the production of hydrogen it will be able to get to work more quickly than by producing the hydrogen in this country. The electrolytic-hydrogen plant in Norway has a daily capacity of over 9,000,000 cu.ft.

Claude's experimental work has shown very clearly that for a given temperature the proportion of nitrogen and hydrogen remaining combined under conditions of equilibrium increases rapidly with rise of pressure, and that the lower the temperature the higher is the proportion of combination. However, the lower the temperature the longer it takes to reach equilibrium, so that a compromise is necessary. Claude finds it best to work at 600 deg., and he uses a pressure of 900 atm., or nearly 6 tons per sq.in., as against the 200 atm. used by Haber. The hydrogen and nitrogen, mixed in the proper proportions, are first compressed to 100 atm. in an ordinary three- or four-stage compressor, passed through separating bottles, where any condensed moisture and oil from the compressor are drained off, and the gas mixture thence goes to the supercompressor. This is a simple two-stage machine capable of dealing with enough gas to make 5 tons of liquid ammonia per 24 hours—i.e., 426 cu.ft. per minute. One of these machines has been running in France for 9 months without trouble.

Small Pipe-Work Facilitates Gas-Tight Joints

An important result of working at superpressure is that the pipe-work becomes small; the pipes carrying the mixed nitrogen and hydrogen for a plant making 5 tons of ammonia per day are only 8 mm. bore, and the difficulty of making gas-tight joints is thereby greatly reduced.

Quite small catalyst vessels can be used which can be heated initially by external electric circuits, and after that the problem is to get rid of the excess heat. A Haber catalyst vessel for 20 tons of ammonia per day weighs 74½ tons, against 11¼ tons for Claude tubes. In the Claude plant there are four catalyst tubes, the first two of which are parallel, and the other two in series with the first two and with each other. The Claude tubes are of special chromium alloy without a lining. Some of these tubes have been made in France, and some in England by Messrs. Vickers, who use a metal called Vicronic which is said to have remarkable heat-resisting properties. The tubes are cast solid and bored out. The basis of the catalyst used by Claude is peroxidized iron prepared by burning iron in oxygen, with the addition of other equally cheap materials which are added in order to increase its activity and immunity from poisons.

Another important detail in the Claude process is the manner of removing the ammonia from the catalyst tubes. Under the Haber conditions it is necessary to inject water into the system and thereby recover the ammonia as an aqueous solution, leading to consumption of power and plant complication. At 900 atm., however, simple cooling by a coil immersed in water suffices to liquefy the whole of the ammonia with the exception of 2 or 3 per cent, and this small quantity is easily removed from the residual gases either by further cooling produced by the vaporization of part of the ammonia or by absorption in sulphuric acid.

Cheap hydrogen is essential to the commercial success of synthetic ammonia and the most economical source at present is the existing coke ovens. In countries where cheap water power is available electrolytic hydrogen becomes attractive.

The packing of the stuffing boxes in the Claude apparatus is merely a single hydraulic leather. The Haber plant requires three days to heat up after being allowed to get cold, whereas the Claude plant will begin to produce again in four to five hours. The tubes in the Claude process are encased in ferro-concrete containers for safety.

Notes on the Chemistry of Chromyl Chloride

By Elton Richmond Darling

THE experimental work which is being carried out with chromyl chloride, CrO_2Cl_2, in the manufacture of organic dyes and compounds gives evidence of its greater use.

The literature on the subject is not extensive and the following notes may be of service to those interested.

The first mention in the literature of chromyl chloride is that of Thomsen (*Phil. Trans.*, 1827, p. 159), who claimed to be its discoverer. Thomsen prepared it by fusing a mixture of 20 parts of sodium chloride and 24 parts of potassium bichromate with 60 parts of concentrated sulphuric acid. It was purified by repeated crystallization. He also prepared it by heating chromium trioxide in a current of hydrochloric acid and distilling to separate the chlorochromic acid which was also formed. This product was investigated by Berzelius and Wöhler (*Pogg. Ann.*, 1834, vol. 33, p. 343).

Geuther (*Ann.*, vol. 106, p. 239) prepared it by heating equal parts of chromic anhydride and ferric chloride together in a retort. He also prepared it (*Ann.*, vol. 118, p. 69) when chromic anhydride and chromic chloride were heated together in a ratio of 2 parts of the former to 3 parts of the latter.

Schiff (*Ann.*, vol. 106, p. 116) prepared it by heating 1 part of chromic anhydride and 2 parts of phosphorus pentachloride together. He further stated that it could be prepared (*Ber.*, vol. 10, p. 104) by suspending chromic anhydride in concentrated sulphuric acid and passing in hydrogen chloride.

Moissan (*Ann. Chim.* (6), vol. 5, p. 568) prepared it by passing hydrogen chloride over chromic anhydride.

Etard (*Ann. Chim.*, vol. 5, p. 218) prepared it by the method of Thomsen and obtained a yield of 70 per cent of theory. He carried out the distillation several times in the presence of carbon dioxide gas.

E. Moles and L. Gomez (*Z. physik. Chem.*, vol. 80, pp. 513-30) prepared the chromyl chloride by the method of Thomsen except they used fuming sulphuric acid in place of the ordinary sulphuric acid.

H. Moissan (*Compt. rend.*, vol. 98, pp. 1581-1583) prepared it by submitting chromic anhydride to the action of a mixture of chlorine and hydrochloric acid and then heating the whole to 150 deg. C. He further states that the chromates of the alkalis, barium, lead and silver all give chromyl chloride when treated with hydrogen chloride. He further states (*Bull Soc. Chim.*, vol. 43, p. 6) that it can be prepared by using chlorine and steam in place of the hydrochloric acid, but the reaction is not possible if only the dry chlorine is used.

H. D. Low and F. M. Perkins (*Proc. Chem. Soc.*, vol. 23, p. 11) obtained a nearly theoretical yield by dissolving chromic acid in more than the equivalent of concentrated hydrochloric acid and then adding to the solution concentrated sulphuric acid in small amounts until the chromyl chloride separated out as a heavy underlayer which was drawn off. This was purified by blowing air through it and then distilling.

Thomsen (*Phil. Mag.*, 1827, p. 452) prepared ammonium chloride from chromyl chloride by passing its vapors into a vessel of dry ammonia gas. This was, however, but one of the products formed.

Wöhler (*Ann.*, vol. 60, p. 203) found that upon heating chromyl chloride to a dull red heat it was decomposed, splitting up into chromic oxide, oxygen and chlorine.

V. Thomas (*Compt. rend.*, 1899, vol. 129, pp. 828-831) treated chromyl chloride with nitric acid, which resulted in the formation of higher nitrogen oxides. He then investigated and studied a series of double compounds prepared from it.

Liebig (*Pogg. Ann.*, vol. 21, p. 359) in carrying out some research work on chromyl chloride believed that he had prepared metallic chromium when brown fumes resulting from the action of chromyl chloride vapors upon dry ammonia were obtained.

G. Odde and E. Serra (*Gazz. chim. ital.*, 1899, vol. 29, ii, pp. 318-329) carried out work on the polymerization of inorganic chloro-anhydrides.

P. Pascal (*Compt. rend.*, 1909, vol. 148, pp. 1463-1465) treated chromyl chloride with dry nitric oxide and produced chromyl subchloride. This product he found to possess strong magnetic properties.

G. G. Henders and I. M. Heilbron (*J. Chem. Soc.*, vol. 99, pp. 1887-1901), in their work on the chemistry of the terpenes, investigated the action of chromyl chloride upon bornylene.

C. Pagel (*Chem. Centr.*, 1900, vol. 2, p. 784) used chromyl chloride to destroy organic substances in toxicological analysis.

Sell (*Proc. Roy. Soc.*, vol. 33, p. 267) found that no chlorine was formed when chromyl chloride was heated with carbamide.

R. F. Weinland and M. Fiederer (*Ber.*, 1906, vol. 39, pp. 4042-4047) found that when the chlorides of the alkali metals were treated with chromyl chloride double salts were formed.

E. Beckmann (*Z. anorg. Chem.*, vol. 77, pp. 90-102) studied chromyl chloride as an ebullioscopic solvent.

E. Moles and L. Gomez (*Anales soc. españ. fís. quím.*, vol. 12, pp. 142-154) made extensive studies regarding the properties of chromyl chloride and its action toward various chemicals.

S. Rideal (*J. Chem. Soc.*, 1886, vol. 49, pp. 367-368) made a quantitative study of the action of ammonia upon chromyl dichloride.

D. Spense and J. C. Galletly (*J. Am. Chem. Soc.*, vol. 33, pp. 190-194) noted that as a result of treating various rubbers of different botanical origin with chromyl chloride a compound was formed which was analogous to a compound that resulted when terpenes were similarly treated.

A. Haller (*Compt. rend.*, vol. 84, pp. 558-559) prepared anthraquinone by dissolving anthracene in glacial acetic acid and treating this to the action of chromyl chloride.

H. S. Frey and J. L. Donnelly (*J. Am. Chem. Soc.*, 1918, vol. 40, pp. 478-482) studied the action of chromyl chloride upon phosphorus halides dissolved in carbon tetrachloride so as to prevent any explosion from taking place. This was a continuation of an earlier work (*J. Am. Chem. Soc.*, 1916, vol. 38, pp. 1923-1928).

H. Quantin (*Compt. rend.*, vol. 104, pp. 223-224) prepared phosgene by the action of carbon tetrachloride upon chromyl chloride. He also noted that carbon monoxide decomposed it with the formation of chromic oxide and chromic chloride.

Jose R. Mourele and A. G. Banus (*Anales soc. españ. fís. quím.*, vol. 9, pp. 355-362) were unsuccessful in their attempt to prepare phosgene by the action of carbon upon chromyl chloride. The products formed were chromic anhydride and chromic chloride.

Corrosion of a Producer-Gas Cooling System

Cooling Water of High Acidity and Containing Much Dissolved Oxygen and Suspended Coke Dust Causes Deterioration of Cooling System at the Plant of the Providence Gas Co., Providence, R. I.—Remedial Measures Are Suggested*

By LLOYD E. JACKSON

THE manufacturing plant of the Providence Gas Co. has been described in detail in articles published recently.[1] It is sufficient to mention here that the plant as a whole consists of coal-gas and water-gas plants, with auxiliary equipment necessary for their operation.

The gas producers, five in number, were designed to produce gas from coke or from bituminous coal, either with or without recovery of ammonia. However, under existing conditions, the producer plant did not operate successfully with bituminous coal. Some minor changes were made and the producers were put in operation again with small-size coke for fuel instead of bituminous coal. After six months' operation with coke, leaks developed in the producer-gas cooling-water system and a thorough investigation was undertaken to determine the causes and remedies for the deterioration of the piping and other iron parts. The writer, an Industrial Fellow of the Mellon Institute of Industrial Research of the University of Pittsburgh, was assigned to conduct the investigation, and it is the purpose of this article to discuss the results of eight months of extensive tests, analyses and observations.

FIG. 1. PANORAMIC VIEW OF THE PLANT OF THE PROVIDENCE GAS CO., PROVIDENCE, R. I.

Fig. 4 is a line-drawing of the producer-gas cooling system as the plant was operating when the greatest number of leaks developed. Starting at the coke filters near the spray pond, cool water is distributed to the dust catcher, collecting main and condenser sprays. From here the water, after coming in contact with the hot producer gas, falls into the decanter below and is pumped to the spray pond, cooled, and again pumped through the same cycle. Make-up water from the city water mains enters the system over the tops of the producers and through the separator. During the eight months of testing, one leak, the first in that line, developed in the 10-in. pipe line conveying cooled water from the coke filters to the producer plant. Leaks occurred in the small distributing pipes which carry cool water to the dust catcher and collecting main sprays. Most of the leaks developed in the 6-in. pipe line which conveyed warm water from the decanter to the cooling pond, a distance of approximately 550 ft. It has been necessary to renew every piece of this pipe line at least once and parts of it have been renewed twice. The impellers in the centrifugal pumps which pump the cooling water to and from the cooling pond also gave considerable trouble. Those in the pumps pushing water from the decanter to the cooling pond had to be renewed more frequently than those bringing water back.

Four Possible Causes for the Deterioration

It was decided that the deterioration of the cooling-water system could be due to any one or a combination of two or more of four causes, as follows: (1) electrolysis caused by stray electric currents; (2) free mineral acid; (3) suspended erosive matter, and (4) dissolved oxygen. Observations made from time to time during the investigation tended to discourage the probability of stray currents being a factor in the problem. In the first place, tests with a millivoltmeter failed to indicate any difference in potential between various parts of the piping system. In the second place, the general nature of the corrosion was not characteristic of electrolysis by stray currents. Corrosion of pipe lines due to stray currents causes very rapid corrosion at points where the current leaves the line, while at other places in the line the pipe will appear practically untouched. If the producer-gas cooling-water pipes carried a stray electric current, that current would have

to enter and leave the line at certain points. At the point or points where it would leave the line, marked corrosion would take place both on the outside and inside of the pipe, while other parts of the line would last indefinitely. Furthermore, if corrosion were caused by stray currents, the pipe line from the producer plant to the cooling pond would not corrode so much more rapidly than the pipe line conveying the water from the cooling pond to the producer plant. One more argument, and a convincing one, against the probabilities of stray currents being a factor in the problem is the fact that during the time that the plant has operated with bay water for producer-gas cooling, which totals almost five months, fewer leaks have developed than was the case with fresh water. If the pipe lines were carrying stray currents, the much greater concentration of dissolved salts in bay water would tend to increase corrosion greatly and develop more leaks than would develop with fresh water.

FIG. 2. CRUSHER BUILDING AND COAL-CONVEYING MACHINERY

As a step to determine the cause of the trouble, samples of water were collected from the producer-gas cooling system at the places marked in Fig. 4 with numbered arrows. Complete mineral analyses of these samples were made and the results are presented in Table I.

One of the characteristic properties of the cooling water which might cause corrosion is acidity. Acid was found not only in the samples analyzed and reported in Table I, but also in numerous check samples collected later. It is well known that even traces of free mineral acids in water cause the rapid corrosion of pipe lines carrying it. The most economical way to treat acid water is to neutralize it with lime, but before starting to treat the water to correct its corrosive properties, some carefully cleaned test-pieces of iron, 5 in. x 2 in. x ⅛ in., were suspended by means of a piece of wrapping cord in the cooling system at the same points from which water samples were collected. The test-pieces were allowed to remain several days and then were removed, dried and weighed. Losses per sq.in. of exposed surface were calculated and the results are presented as test 1 in Table II. This test was made to obtain data with which to compare future data to be obtained from tests made following successive steps in treating.

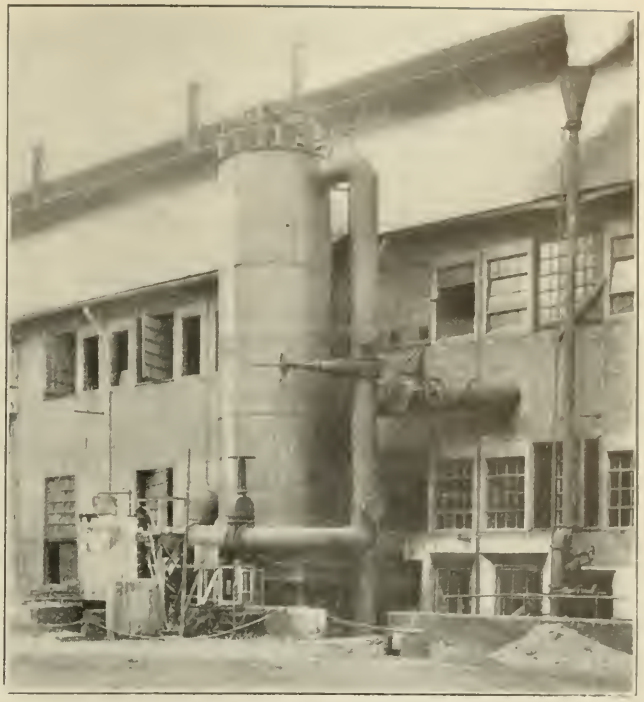

FIG. 3. EXTERIOR OF THE PRODUCER-GAS PLANT, SHOWING CONDENSER, EXPERIMENTAL LIME-TREATING APPARATUS AND DECANTER

Apparatus to treat the water with lime next was installed. At first the water was treated with sufficient lime to make it alkaline to methyl orange indicator. During this time the same test-pieces of iron were suspended in the cooling system at the same points as described for test 1. The weights lost per 24 hours per sq.in. of exposed surface are shown by test 2 in Table II. The results of these two tests show that the corrosion of iron is about one-half as great when the water

TABLE III. DISSOLVED OXYGEN IN SAMPLES OF WATER COLLECTED FROM THE PRODUCER-GAS COOLING SYSTEM

Location	City Water Tap in Exhauster Room	Intake Spray Pond Pump	Weir From Prod. House	Overflow From Ash Pan	Decanter After Condenser	Left Coke Filter
Temperature (deg. F.)	73	122	131	136	131	93
Dissolved oxygen (p.p.m.)	4.6	2.3	2.2	3.8	1.4	5.2

is treated with sufficient lime to make it alkaline to methyl orange. Figuring the quantity of lime used on a basis of 100 per cent CaO, from 50 to 100 lb. per day was required to maintain the decanter water alkaline to methyl orange. The variation in quantity of lime required was due to operating conditions in the producers and to the number of producers in line.

Methyl orange indicates free mineral acid only, while phenolphthalein shows acidity caused by dissolved carbon dioxide as well as the free mineral acid resulting from the hydrolysis of iron salts. An attempt was made to treat the decanter water with sufficient lime to maintain it alkaline to phenolphthalein; but, due to the presence of carbon dioxide in the producer gas with

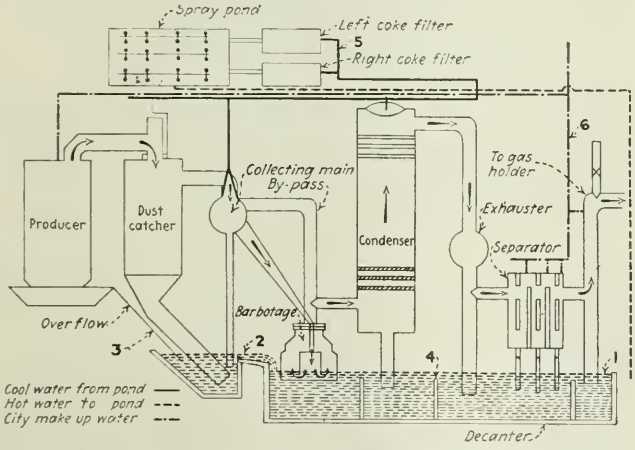

FIG. 4. PRODUCER-GAS COOLING SYSTEM. NUMBERS INDICATE POINTS AT WHICH WATER SAMPLES WERE TAKEN

which the cooling water came in direct contact, so much lime was required to maintain the water alkaline to phenolphthalein that it was not considered a practical method of treatment.

About the same time that samples were collected for mineral analyses more samples were taken from the decanter at the same points and analyzed for dissolved oxygen. The results are presented in Table III.

Many more samples were later collected from the cooling-water system and tested for dissolved oxygen. The results obtained were practically the same as reported in Table III. These tests indicated that the city water used for making up evaporation losses was highly saturated with dissolved oxygen. It is also evident that, as the water gives up its dissolved oxygen in the gas-cooling system, it is continually receiving a fresh charge when it is sprayed into the cooling pond.

It is a fact that dissolved oxygen is an active corrosive agent either in a neutral or acid solution. It is particularly active in the presence of free mineral acids. To free the cooling water of dissolved oxygen, it was proposed that the coke in the coke filters be replaced by steel turnings. The dissolved oxygen in the water flowing from the cooling pond through the steel turnings combines with iron to form iron oxide and the water is pumped from the filters oxygen free. Test-pieces of iron suspended in the cooling system, after the installation of the steel-turnings filter, corroded as shown by the results tabulated under test 3 in Table II. For purposes of comparison, test-pieces hung in the decanter near the intake to the cooling pond pump are good examples, because the water at this point was about to enter the pipe line to be pumped to the cooling pond. It was this pipe line that corroded most rapidly. It will be noticed that the corrosion of test-pieces was about one-half as great when the water was maintained alkaline to methyl orange and less than one-quarter as great when treated for dissolved oxygen maintained alkaline to methyl orange (see tests 1, 2 and 3 in Table II.)

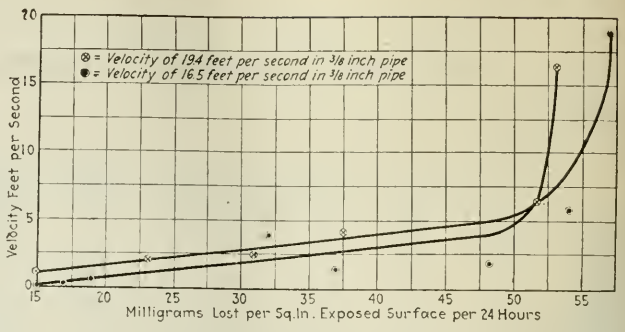

FIG. 5. EROSIVE ACTION OF COOLING WATER CONTAINING SUSPENDED COKE DUST

Erosion Caused by Suspended Coke Dust

To determine the erosive action of the suspended coke dust in the cooling water, apparatus was made up in duplicate consisting of weighed short equal lengths of pipe of different sizes, connected together with reducer couplings, starting with the largest size and tapering to the smallest. One set of testing apparatus was arranged so that the largest nipple was connected to the service pipe carrying the cooling water from the decanter to the cooling pond and the smallest nipple was connected through a valve with a meter so that the rate of flow through the pipes could be regulated. The other piece of apparatus was arranged so that the smallest nipple was connected to the service pipe and the largest nipple to a valve and meter. The rate of flow through the largest nipple was regulated to be less and the rate through the smallest nipple was regulated to be considerably greater than the rate of flow through

TABLE IV. RESULTS OF EROSION TEST WITH PRODUCER-GAS COOLING WATER

Pipe Size	Average Velocity Water During Test Ft./Sec.	Total Grams Lost	No. of Days in Line	Milligrams Lost per Sq.In. Exposed Surface	Milligrams Lost per Sq.In. per 24 Hr.
Direction of Flow Through Large Pipe Toward Smaller Pipe					
¾x24 in.	16.5	25.650	13	690	53
¾x24 in.	5.9	81.200	24	1,305	54

the 6-in. service line between the decanter and the cooling pond. Water from the 6-in. service pipe was permitted to flow through the apparatus for 24 days. The apparatus then was dismantled, and the short pieces of pipe were reweighed and the weight lost per sq.in. of the exposed inner surface calculated. The results are presented in Table IV and plotted against water velocity in Fig. 5. Daily determinations of suspended matter in the cooling water made over a period of about two weeks showed a variation between 24 and 140 parts per million. Results of proximate analyses of samples of this suspended matter are shown in Table V.

TABLE V. PROXIMATE ANALYSES OF SUSPENDED MATTER IN PRODUCER-GAS COOLING WATER WHEN USING RECIRCULATED FRESH WATER (PER CENT)

Source	Shoveled From Bottom of Inside Decanter	Shoveled From Outside Decanter	Filtered From Water Collected Near Intake to Pump
Volatile matter	7.71	2.13	51.2
Fixed carbon	59.01	78.76	
Ash	33.28	19.11	48.8

Calculating Life of 6-In. Pipe

It is quite evident that erosion due to suspended coke dust and ashes plays a very important part in the deterioration of the cooling system.

Pitot tube readings indicated that the velocity of water in the 6-in. service pipe from the decanter to the cooling pond is approximately 12 ft. per second under average operating conditions. The erosion test showed this pipe to be wearing away at the rate of 55 mg. per sq.in. per 24 hours. From data presented in Table IV and from some measurements of standard 6-in. pipe, some interesting figures are presented below:

Thickness of standard 6-in. pipe = 0.3 cm. bottom of threads to inside surface.[2]

1 sq.in. of pipe, 0.3 cm. thick = 1.935 c.c. of iron and weighs 15,450 mg.

The life of 6-in. pipe eroding at the rate of 55 mg. per day is therefore 15,450 ÷ 55 = 281 days, or 9 months and 11 days.

During the period of the erosion test the water in the decanter was maintained alkaline to methyl orange and freed from dissolved oxygen. Test-pieces of iron hung in the decanter where they were not subject to the erosive action of suspended coke dust lost weight at the rate of 3.6 mg. per sq.in. per 24 hours. At this rate of corrosion a standard 6-in. pipe will last for more than 10 years. This figure represents what might be expected with treated and filtered fresh water.

Recommendations and Suggested Remedies

Having determined the causes for the deterioration of piping and other equipment in the producer-gas cooling system, the following remedies were suggested:

(1) Cool and clean the producer gas with fresh water, and permit the water to waste to the bay after going through the cooling system. (2) Treat, cool and recirculate fresh water. The treatment recommended consists of filtration to remove suspended coke dust, neutralization of free mineral acid with lime, and removal of dissolved oxygen with steel turnings. (3) Cool and clean the gas with an excess of bay water and let it waste back to the bay. A brief discussion of each remedy follows.

Fresh water can probably be obtained most economically from wells. This water, freed of dissolved oxygen, if there is any present, by means of steel turnings, would cause the least corrosion of any of the remedies mentioned. Treated and recirculated fresh water would have its deleterious properties removed and would cause very little, if any, more corrosion than fresh water not circulated.

Experiments With Bay Water

The average of several analyses shows that bay water pumped from near the gas plant has about two-thirds as many dissolved solids as sea water and that the solids are similar in character to those in sea water. It is known that sea water is an active corrosive agent, particularly when hot. Accordingly, tests were made with special apparatus and under actual working conditions with bay water for cooling producer gas to determine the degree of its corrosive action under the conditions existing in the producer gas plant.

In test 4, Table II, are presented results of a test to determine the corrosive action of cold bay water before and after removing its dissolved oxygen. The water in this case had a temperature between 70 and 75 deg. F. It will be noticed that cold deactivated bay water had no appreciable corrosive action on iron. From this experiment the conclusion was drawn that the piping and cooling equipment handling cold bay water would not corrode very rapidly. There probably would be more corrosive action than this test indicated at points in the system where there is chance for galvanic action—e.g., where brass and iron are in contact. This action could be reduced by using iron valves and fittings in pipe lines. Table II also gives a very good comparison between the action of cold bay water and fresh water.

Effects of Increased Temperatures

Sea water, in this case bay water, is more corrosive at higher temperatures than it is when cold. This property is due to the presence of calcium chloride and particularly magnesium salts. For example, magnesium chloride hydrolyzes to form hydrochloric acid and the latter readily reacts with iron. The extent of this reaction increases as the temperature rises. Because of this property of bay water, tests were made to determine its corrosive action in the presence of hot producer gas. These tests were made with raw bay water and with deactivated bay water—i.e., bay water from which the oxygen had been removed by passing through steel turnings. The results of these tests are presented in Table VI.

Comparing test 1, using raw bay water, with test 2, using deactivated bay water, it will be noticed that, in the presence of deactivated bay water, iron corrodes about three-fifths as rapidly as in the presence of raw bay water; also that, when using either raw or deactivated bay water, its corrosive action increases rapidly as the temperature rises. Test 3 was made at a higher temperature than test 2 and shows a correspondingly greater corrosive action. Test 4 with deactivated city water shows that, at a high temperature, there is some corrosive action in the presence of fresh water and producer gas. Tests 5 and 6 were made with weighed test-pieces of pipe resting on the bottom of a dustcatcher, which is probably the hottest part of the cooling system and where the most corrosion would take place when using salt water. These results agree closely with the results of tests 1 and 2. In the column "Calculated time to corrode through ¼-in. stock of dustcatcher, etc.," are figures obtained by dividing the weight of a sq.in. of

[2] Practically all the leaks in the cooling-water piping system developed near joints where threads cut in the pipe had made the iron thinner than the remainder of the pipe.

iron ¼ in. thick by the average milligrams lost per sq. in. per 24 hours by test-pieces of pipe during each test, and converting this result to years and months. The figures in this column may be considered the life of the cooling system at its weakest point under varying conditions when using bay water to cool producer gas. The farther away from the dustcatcher the gas travels the cooler it gets; therefore the life of the collecting main and condenser should be longer.

TABLE VI. CORROSION OF TEST-PIECES OF PIPE IN THE PRESENCE OF HOT PRODUCER GAS AND BAY WATER AND HOT PRODUCER GAS AND FRESH WATER

Test No.	Location of Test-Pieces	Days Duration of Test	Approximate Temp. of Test, Deg. F.	Kind of Water and Condition	No. of Test-Pieces of Iron Subject to Condition of Test	Av. Mg. Lost per Sq.In. per 24 Hr.	Calculated Time to Corrode Through ¼-In. Stock of Dust-catcher, Etc.
1	In joint 6-in. pipe near No. 1 producer	14	130–160	Raw bay water	4	25	3 yr. 4 mo.
1	Ditto.....	14	100	Ditto.....	2	18	4 yr. 8 mo.
1	Ditto.....	14	70–80	Ditto.....	4	8	10 yr. 7 mo.
2	Ditto.....	14	130–160	Deactivated bay water	4	16	5 yr. 3 mo.
2	Ditto.....	14	100	Ditto.....	2	8	10 yr. 7 mo.
2	Ditto.....	14	70–80	Ditto.....	4	5	17 yr.
3	In nipple on top of dust-catcher No. 3	14	230–260	Ditto.....	7	30	2 yr. 10 mo.
4	Ditto.....	14	230–260	Deactivated city water	7	10	8 yr. 6 mo.
5	In bottom of dustcatcher No. 3	14	90–100	Raw bay water	6	22	3 yr. 10 mo.
6	In bottom of dustcatcher No. 3	14	110–120	Deactivated bay water recirculated from end of decanter	9	20	4 yr. 3 mo.

When 60 deg. F. or cooler water is available, the producer gas can be cooled sufficiently by pumping the cold water over the condenser and pumping warm water from the decanter over the dustcatchers and collecting main. To determine whether warm bay water causes greater corrosion under these conditions, weighed pieces of iron were suspended on the bottom of a dustcatcher and permitted to remain there for 14 days; then they were removed and reweighed. Water entered the dustcatcher at a temperature of 100 to 110 deg. F. and left at a temperature of 110 to 120 deg. F. The results are presented in test 6 of Table VI, and show that practically the same amount of corrosion takes place in the dustcatcher as when cold water which has not been deactivated is pumped. This recirculation, whether with bay water or fresh water, should not be practiced, because the water when tested contained 50 to 70 p.p.m. of suspended coke dust. Under these conditions, it is to be expected that pipes and pumps carrying the water from the decanter to the dustcatchers will erode rapidly. Bearing out this contention, several leaks developed while test 6 was in progress.

Because of the deleterious action that dissolved salts in bay water would have on the refractories if carried over with the producer gas when the latter is burned in the coke-oven battery, some tests were made to determine if the gas carried any of these salts while bay water was used for cooling.

The results of the tests showed that a small quantity of chloride was being carried over. Further tests indicated that this must have been due to hydrochloric acid, probably derived as a product of the hydrolysis of magnesium chloride at high temperatures.

When chlorides were found in the gas, the producers were delivering gas at times at a temperature of 1,700 to 1,800 deg. F. Since that time numerous tests have been made when the producers were delivering gas under 1,400 deg. F., and only traces of chlorides were found in distilled water through which more than 100 cu.ft. of producer gas was passed. One sample through which gas had been passed was analyzed for magnesium, which is a common substance found in sea water, but only a trace was found. The conclusion reached after these tests is that no bay water salts are carried into the battery when bay water is used to cool producer gas.

Comparing Bay Water With Recirculated Fresh Water

Comparing tests made when using bay water for cooling producer gas and permitting the water, after passing through the system once, to waste to the bay, with tests made with unfiltered recirculated fresh water, it is obvious that the advantage lies with bay water. Tests show the life of the weakest points of the cooling system to be approximately nine months when recirculating unfiltered fresh water, compared with three to four years when using cold deactivated bay water. However, at best the use of bay water can be considered as being merely the lesser of two evils. Tests indicate that with an abundant supply of fresh water which can be allowed to waste to the bay after going through the cooling system once or with recirculated fresh water which has been treated and filtered, the life of the weakest point in the cooling system will be ten years or more. These figures must be qualified to the extent that they were calculated for a cooling system not deteriorated. There are probably places in the cooling system which are almost corroded through, due to having recirculated water containing suspended coke dust, and, no matter what change is made in the cooling water, these places will give way sooner than calculated above. In order to know which is the best of the three remedies discussed, it must be known which is the most economical.

Consideration of Costs

The most economical source of fresh water in sufficient quantities so that it can be wasted to the bay after going through the cooling system once is a series of wells drilled adjacent to the plant. The total cost of cooling the producer gas by this means will be the cost of drilling wells plus the cost of pumping through the cooling system.

To cool the gas with treated and filtered water, it will be necessary to install sand filters and lime-treating apparatus to handle approximately 2,000,000 gal. of water daily with the present cooling apparatus. This could be cut to 1,000,000 gal. per day with more efficient cooling apparatus. The total cost of cooling producer gas under these conditions will be the original cost of installing the treating and filtering apparatus plus their upkeep and operation, together with the cost of pumping to and from the cooling pond and the cost of city water to make up for evaporation losses.

The cost of using bay water will entail the expenses due to pumping the water plus the extra cost of upkeep in the cooling system, which will mean the renewal every three or four years of those parts of the cooling system that come in contact with the cooling water and the hot gases.

Manufacture of Pyroxylin Plastics

Properties of Celluloid—Methods of Mixing the Cellulose Nitrate With Camphor and Alcohol—Stabilizing—Filtering—Rolling—Baking—Sheeting—Polishing—Manufacture of Rods and Tubes—Scrap Utilization—Camphor Substitutes and Synthetic Camphor—Chemical Control

By J. R. DuPONT

WHEN cellulose nitrate prepared according to the methods outlined in a previous article[1] is mixed with camphor and denatured alcohol, plastic products result which are usually referred to as celluloid,[2] although it would be more correct to call them pyroxylin plastics. Sometimes for the sake of economy the camphor and alcohol are replaced partly or entirely by substitutes which will produce a more or less satisfactory celluloid.

Pure celluloid is a transparent substance having a density of about 1.35. It is a poor conductor of heat and electricity. The tensile strength varies from 6,000 to 10,000 lb. per square inch. It cannot be exploded by percussion or pressure. Exposed to a flame, it softens and takes fire rapidly, evolving very disagreeable fumes resulting from the volatilization of the camphor and also from the nitrous gases produced by the decomposition of the cellulose nitrate. Heated without compression, celluloid starts to decompose around 125 deg. C., the action being accelerated by increasing the temperature—around 165 deg. C. the decomposition is complete. If kept in hot water at about 85 deg. C., celluloid is softened enough to permit the molding of objects which will retain the shape of the mold after cooling.

Although almost insoluble in water, celluloid is soluble in acetic, propionic, nitric and sulphuric acids, the latter two causing decomposition. Strong alkalis also decompose celluloid, and this property is used in the recovery of camphor from unusable celluloid scrap.

Celluloid is slightly soluble in ethyl alcohol and is soluble in methyl alcohol; ethyl, methyl, butyl and amyl acetates; ethyl propionate, acetine; diacetine; triacetine; epichlorhydrin; dichlorhydrin; and alcohol solutions of camphor, acetanilide, methylacetanilide, chloral hydrate, tricresylphosphate, triphenylphosphate, tribenzylphosphate, etc.

Mixing the Cellulose Nitrate and Camphor

Turning now to the manufacture of celluloid, the first operation consists in mixing the cellulose nitrate with camphor and alcohol so as to produce a gelatinized mass. The mixing may be done in boxes or by machine.

Mixing in Boxes.—When in slab form, the dry cellulose nitrate is first broken into small pieces in a specially constructed machine and then placed in heavy rectangular galvanized-iron boxes having sloping sides. Camphor alcohol solution or denatured alcohol is sprinkled on and mixed by hand with wooden paddles. These boxes are covered air tight and placed in a room where the temperature is kept around 30 deg. C. After 24 hours the mass is more or less gelatinized and ready to be rolled. This method requires from 50 to 60 per cent of alcohol when 35 per cent of camphor is used, and because of the high percentage of alcohol used and the time required, nearly every factory has abandoned this process for the following one:

Mixing by Machine.—The cellulose nitrate is dumped into a kneading machine in which two specially shaped steel blades turn in opposite directions, assuring a constant and thorough mixing of the cellulose nitrate with the camphor and alcohol. Camphor (if not previously mixed with the cellulose nitrate) is added and also the denatured alcohol, and the machine is kept in motion for about 1 hour. After this time the mass is completely mixed, but not converted, and at this stage is placed in galvanized-iron boxes which are transferred to a warm room, where they stay long enough to permit partial conversion of the cellulose nitrate.

A far better and quicker way to produce the gelatinization of the cellulose nitrate is to use a jacketed kneading machine which will permit heating of the cellulose nitrate, camphor and alcohol and produce a complete conversion in about 1 hour's time. The heating is done with hot water and complete control of the temperature is necessary. Generally it is not permitted to go above 60 deg. C. This method of mixing reduces not only the time of the operation but also the quantity of denatured alcohol required to obtain a good conversion and with a good grade of cellulose nitrate only 40 per cent of alcohol is necessary. As the conversion is complete, the subsequent operation of rolling is shortened.

Some factories prefer to use more alcohol for the conversion, say 55 to 65 per cent of the weight of the cellulose nitrate, and after the conversion has been effected, reduce the alcohol contents to about 30 per cent, using vacuum as means of recovery. To obtain this recovery the mass is first heated to around 60 deg. C. and as soon as the conversion is obtained the mixing box is connected with the vacuum pump. By raising the temperature the alcohol vapors are removed by the pump and after being cooled are collected in a tank. We think that it is better to use around 45 per cent of denatured alcohol for the conversion, because the recovery of an excess of solvent requires longer heating which may result in discoloration of the paste.

In any of the methods used, the temperature of the kneading machine has to be always the same, as a difference in the heating temperature will give a variation in color—particularly in the manufacture of transparent and ivory—which is termed "off-color."

When cellulose nitrate containing alcohol is used, the gelatinization can be accomplished more quickly and more completely than when dry cellulose nitrate is employed; also, and of great importance, the chances of accidents during the mixing are reduced to a minimum.

The author reserves the right of publication and translation of this article.

[1] "Manufacture of Cellulose Nitrate for Pyroxylin Plastics," CHEM. & MET. ENG., vol. 26, No. 1, p. 11, Jan. 4, 1922.

[2] Although celluloid is a trade name, it has become rather firmly established in the literature as a designation for pyroxylin plastics, and this usage has been followed in this article.

Often in using dry cellulose nitrate in slab form, the slabs are not broken in small pieces before mixing, and the excess pull necessary to start the machine may develop sufficient heat to ignite the cellulose nitrate dust and thus cause the explosions which occur from time to time, often with fatal results. By using the proper kind of kneading machines and breaking up the slabs the mixing of dry cellulose slabs is safe. The percentage of moisture in the cellulose nitrate affects the results of the conversion and when above 5 per cent, poor results can be expected. The quantity of alcohol necessary for good conversion of the cellulose nitrate varies with the solubility and viscosity, but at least 40 per cent of denatured alcohol is necessary.

Stabilizing

Celluloid made with a good grade of cellulose nitrate will keep its original color and structure for years, but as a preventive measure every manufacturer stabilizes his celluloid. The stabilizing agent will check any gradual development of acidity and for this reason is generally called an antacid. For white and ivory colors no antacids are used, as the pigment added to the cellulose nitrate, which is usually zinc oxide, will act as stabilizer. But for transparent, shell and other translucent stock, antacids must be used. These must be soluble in alcohol, impart no cloudiness to the finished celluloid, and reduce to a minimum the discoloration due to exposure to light. Many different antacids have been recommended, but the most used are urea, calcium lactate and zinc acetate for transparent celluloid, magnesium oxide and magnesium carbonate for the translucent or opaque stocks.

So as to obtain a perfect mixing of the antacid with the cellulose nitrate, which is essential, the addition of the former is generally made during the kneading operation. The quantity employed varies from 1 to 2 per cent of the weight of the cellulose nitrate. The study of antacids is very important, especially for transparent stock, since by selecting the proper one it is possible to obtain a transparent which will keep its original color instead of shortly becoming discolored, as is the case with many of the celluloid curtains used on automobiles.

Filtering

In spite of all precautions taken during nitration, washing and drying, it is very difficult to obtain a cellulose nitrate which will be absolutely clean and which will produce a first class celluloid. To remove these impurities or specks from the cellulose nitrate paste, it must be filtered. Two different kinds of machinery are used for this purpose. The first is a hydraulic press of the same type as used in the manufacture of celluloid tubes, but of larger capacity. The celluloid paste is heated around 65 deg. C. and pushed through a metallic or camel's-hair screen under a pressure of 3,000 to 3,500 lb. per square inch.

The other method consists in using a mechanical screw filter (Fig. 1) which is composed of a jacketed semi-steel cylinder 40 x 12 in. having two separate jackets so as to regulate the temperature of the cylinder. In the cylinder is a revolving steel worm of varying pitch which can also be heated by means of hot water circulation. The head of the machine, made of cast steel, is also jacketed and supports a steel perforated plate 2½ in. thick, on the front of which is placed the material used to filter the celluloid paste, which generally consists of a very fine mesh screen made of bronze wire or special filtering cloth (felt cloth, camel's hair, etc.).

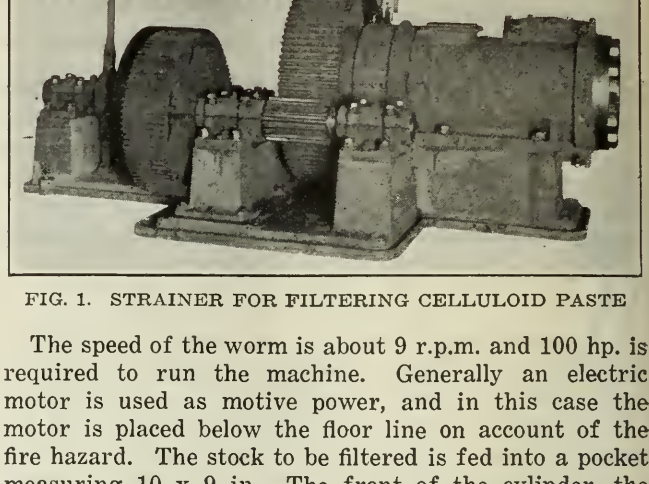

FIG. 1. STRAINER FOR FILTERING CELLULOID PASTE

The speed of the worm is about 9 r.p.m. and 100 hp. is required to run the machine. Generally an electric motor is used as motive power, and in this case the motor is placed below the floor line on account of the fire hazard. The stock to be filtered is fed into a pocket measuring 10 x 9 in. The front of the cylinder, the head and the worm are heated, but the back jacket is kept cool to prevent the stock from working back in the feeding pocket. The temperature is kept around 60 deg. C. by hot water circulation, and a recording thermometer permits the operator to control the heating at all times.

The productive capacity of the straining machine varies very much with viscosity and the alcohol content of the paste to be filtered, the kind of the filtering medium and also with the quantity of impurities to be removed, but generally an average of 400 to 500 lb. of celluloid paste can be filtered per hour. After burning off the impurities metal screens may be used again. In the case of scrap to be worked over, after mixing, it is submitted to a slight rolling before filtration.

Rolling

After mixing, the celluloid paste obtained contains more or less unconverted cellulose nitrate. To obtain a homogeneous paste, the mixed cellulose nitrate is rolled, using two horizontal hollow cylinders made of chilled steel, supported by a heavy frame and turning in opposite directions at about 13 r.p.m. The back cylinder is stationary, but the front roll can be moved, the space between the two rolls being regulated by two screws. Guards prevent the paste from working over the ends of the rolls. Iron pipes going inside the cylinders permit the heating or the cooling of the paste, this being done by steam and cold water. A specially constructed clutch controls the machine, and a safety device is provided for stopping the rotation of the cylinders in an emergency. Above the rolls a hood is generally installed and connected by large galvanized-iron pipes with a fan which carries the alcohol vapors outside of the building, where they are generally lost. The first rolls used were of small diameter varying from 10 to 12 in., but today practically every factory uses rolls of larger diameter—that is, from 18 to 22 in., for a length of 48 to 60 in. Fig. 2 shows a 22 x 60-in. mill with coil clutch.

The rolling process is as follows: The rolls are first heated at different temperatures, the front one, which carries the paste, having a temperature around 55 deg. C. The back roll is heated less, for if too hot the stock will leave the front roll and stick to the back one. The celluloid paste is then dumped on the rolls and the screws regulating the space between the rolls is opened so as to obtain a sheet about ¾ in. thick. At this

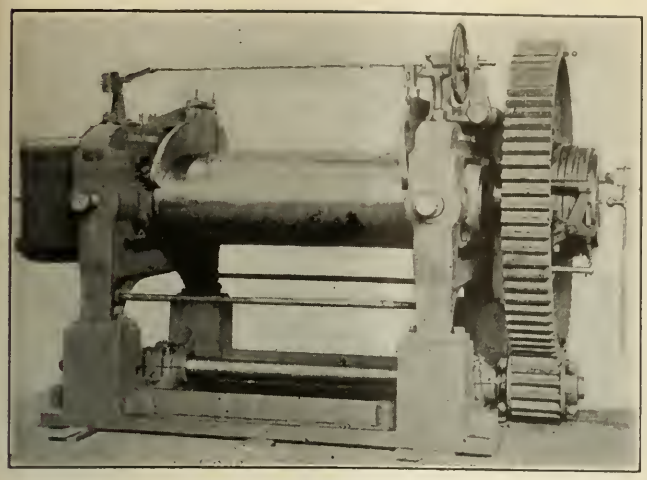

FIG. 2. CELLULOID MILL

stage the dye solutions or pigments are added to the paste according to the color desired. From time to time, the rollman cuts the sheet on the roll with a short knife so as to assure the complete homogeneity of the paste. If the paste is in a bad state of conversion, the screws controlling the front roll are tightened so as to obtain the minimum space between the rolls and thus produce a very thin sheet, which assures the crushing of the non-converted parts. When the operation is judged complete—that is, when the blending is as perfect as possible and the paste has attained the right proportion of solvent to permit pressing—the paste is taken off of the roll and passed again so as to obtain smooth sheets of stock, which are placed on a table of which the top has the dimensions of the plate of the block baking press. When all the paste has been thus sheeted, the sheets are trimmed to the exact size and are ready to be pressed.

The rolls are generally electrically driven and two to eight rolls can be placed on the same shaft. Even with an electric motor of the low-speed type a reducing gear has to be used to obtain the very low speed at which the rolls turn (13 r.p.m.). As to the power required, this varies from 10 to 12 hp. for 12-in. rolls up to 25 to 30 hp. for rolls of 18 to 22 in. diameter. The quantity of paste that can be rolled per hour varies much not only with the quality of the cellulose nitrate and the solvent content, but also with the kind of celluloid to be made. Generally two rolls are working on the same block and they are attended by four men, two rollmen with two helpers. Taking an average of 300 lb. of wet paste to make a finished block, this means that each roll will have to work 150 lb. of paste, which will require from 1¾ to 2½ hours.

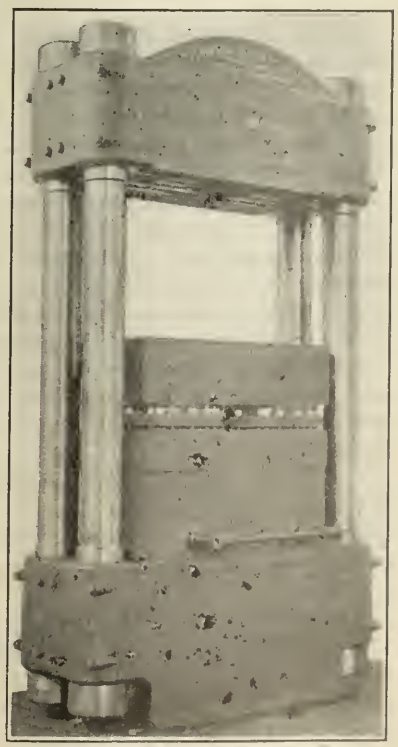

FIG. 3. CELLULOID PRESS

The loss of solvent during the rolling is variable, but as an average 17 to 20 per cent is lost during the operation, the paste going to the baking press containing 16 to 18 per cent of alcohol. The recovery of alcohol lost during rolling has been tried from time to time, but to the author's knowledge no factory has a permanent working installation.

Baking

After rolling comes the baking operation, which when rightly conducted will give a celluloid block absolutely homogeneous. To obtain this result the rolled celluloid is placed in a hydraulic press, where it is heated under pressure so as to obtain a plastic mass. At this stage the mass is cooled under a greater pressure, which operation will expel the air bubbles disseminated in the mass and also completely weld the sheets.

The presses used are composed of a heavy cast-iron bottom yoke, generally cast integral with the cylinder, supporting a plate on which a specially constructed rectangular bender receives the rolled celluloid sheets. Situated above the bender is a rectangular plunger which fits the bender and presses down the celluloid. The plate, the bender and the top plunger are hollow and can be heated by steam or hot water and cooled by water circulation. The rolled celluloid sheets are placed in the press on a semi-steel plate which has the dimensions of the bender and the surface of which has been grooved diagonally, thus permitting the block pressed to be fastened securely to the plate and stand the pulling which occurs during the sheeting.

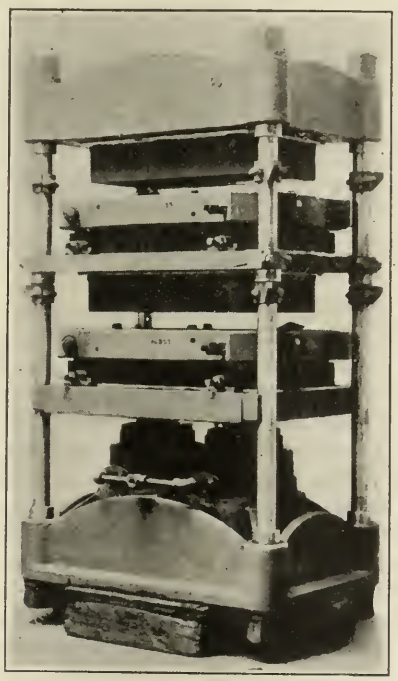

FIG. 4. DOUBLE DECK CAKE PRESS

In the early stage of manufacture the baking presses were made with only one deck and thus only one block was baked per operation. In order to reduce the labor, presses were made with two rams working in opposite directions so as to lift the plunger placed above the bender; by operating the lower ram the block was thus taken off the bender. This type of press is quite extensively used abroad. To obtain a greater production, the next step was the construction of presses with two decks, which would permit the baking of two blocks in the same press. Today most of the presses are made with four benders in which four blocks are baked in one operation. The dimensions of the benders are generally 55 x 23 x 6 in., the dimensions of the pressed block being about the same. Fig. 3 shows a 25 x 58-in. press and Fig. 4 a 23 x 44-in. double deck cake press.

The pressure used during the baking is generally 500 lb. per square inch; during the cooling the pressure is increased up to 3,000 to 3,500 lb. per square inch. The temperature at which the press is heated varies with the duration of the heating, but in no case is this temperature carried above 90 deg. C. On the average, from 4 to 5 hours at 85 deg. C. is required to bake a celluloid block weighing about 300 lb., and the same time for the cooling.

Originally the heating was done with live steam, which gave a very irregular operation, but today hot water is used almost exclusively. The water may be heated in a tank provided with a steam coil, and forced through the press by a centrifugal pump. Placed on the steam line is a regulator which stops the flow of the steam when the correct temperature of the water is reached, the temperature being registered by a recording thermometer.

Preliminary Seasoning of Blocks

After pressing, the celluloid if properly rolled is ready for the sheeting, but if the paste is too soft—and this occurs principally in summer—a preliminary seasoning is necessary. In the early stages of celluloid manufacture the blocks were cooled by cold water which was run on the top of the blocks, but today they are placed in cooling rooms where the temperature is kept around 12 deg. C. by refrigeration. If too soft and left in too warm an atmosphere, the celluloid blocks will be full of pin-holes due to the expansion produced by alcohol vapors.

Sheeting

The sheeting of the celluloid blocks is done on a specially constructed planer (Fig. 5), which is composed of a heavy frame or bed supporting a moving table or platen controlled by a driving screw, on the end of which are two pulleys turning in opposite directions. By means of a clutch either one of the pulleys can be shifted on and thus make the table move forward or backward. On the front of the bed is a knife supported by a frame connected by screws and gears to a controlling shaft which permits the lowering or raising of the knife. The plate supporting the celluloid block to be sheeted is placed upon the table and secured firmly by bolts; the knife is lowered so as to shave the top of the block and obtain a perfectly horizontal surface; then the knife is lowered to obtain the desired thickness, adding to this the known thickness which will be lost during the subsequent seasoning. This allowance varies directly with the final thickness desired. To obtain a sheet 0.010 in. thick the stock is sheeted 0.012 in.; for 0.100 the gage will be 0.113; for 0.200, 0.240, etc. The sheeting machine is generally driven by a 10-hp. electric motor, but 5 hp. is sufficient.

Recently there has been introduced a hydraulic sheeter which is constructed in a similar way to the mechanical one, except that the platen is propelled by a hydraulic ram. The advantages claimed are that this machine permits greater production and a more accurate sheeting, particularly when cutting thin sheets. Also the chances of having the sheets soiled with oil are less. Only a few factories have installed this new sheeter on trial and it is doubtful whether this machine will replace the old type of sheeter, which when rightly handled is very efficient and the cost of which is far less.

As soon as the sheets are cut they are marked so as to know the color, block number, thickness and date of

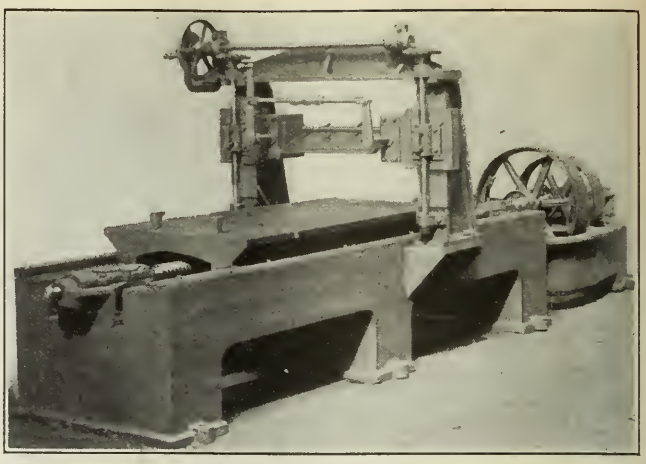

FIG. 5. PLANER FOR SHEETING CELLULOID BLOCKS

sheeting and are placed between special cardboard sheets, where they stay a certain time according to the thickness. During this period a certain amount of solvent is absorbed by the cardboard so that when taken out to be submitted to the real seasoning the sheets will not warp badly and will not necessitate a preliminary pressing before polishing. The cardboard after having been used for a certain time is submitted to a drying operation so as to remove the solvent absorbed. During the sheeting a certain quantity of scrap is made varying with the skill of the operator and also with the constancy and the thickness of the sheeted celluloid. Also a certain amount of imperfect sheets are made. The following shows a good average:

	Per Cent		Per Cent
Imperfect sheets	7 to 9	Scrap	6 to 7
Perfect sheets	82 to 84	Loss by evaporation	2 to 3

The imperfect sheets are sold as seconds and the scrap is sent to the mixing room, where it is worked again.

Seasoning Celluloid Sheets

After they have remained a certain time between cardboard, the sheets are transported to the drying room, where they are submitted to a final drying. Generally the drying is done by hot air circulation. At first the sheets were hung directly above protected steam-heated pipes, but today in most of the plants a fan is used to force the air over a steam-heated coil and then through the drying room, thus giving more uniform seasoning. The temperature of heating is regulated and kept around 38 deg. C. The time of drying is proportional to the thickness of the sheets and Table I shows the duration according to the thickness. During the drying a certain amount of solvent is lost and consequently the weight of the stock is reduced; the following table shows the loss for different thicknesses:

Gage, In.	0.085	0.060	0.090	0.040	0.100	0.085
Before drying, lb.	261	311	284	304	214	245
After drying, lb.	226	263	241	258	179	207
Loss, lb.	35	48	43	46	35	38
Loss, per cent.	13.4	15.4	15.1	15.1	16.3	15.5

The process referred to as "water drying," which is extensively used to dry smokeless powder, finds little application in the drying of celluloid. When used, the celluloid sheets are placed vertically in tanks where water at a temperature of about 45 deg. C. is kept in motion, the "drying" being done by the absorption of

the solvent by the water. This method is much quicker than that of using hot air, but at the end of the process the stock has to be heated so as to remove the water retained by the stock. Vacuum drying if properly conducted is efficient but requires an expensive installation.

During the drying of the sheets about 14 to 15 per cent of alcohol is lost, the recovery of which would represent a large saving, but so far little has been done to avoid this loss, largely because the changes which would have to be made in the present installations and the extra machinery required seem expensive. However, it is reasonably certain that in the case of a factory producing about 3,000,000 lb. of celluloid per year the installation of a system of solvent recovery, for the rolls and drying rooms, will prove a good investment.

TABLE I. TIME OF DRYING CELLULOID SHEETS

Thickness, In.	Time of Drying — Between Cardboard, Days	In Drying Room, Days
0.004 to 0.009	1	2 to 3
0.010 to 0.020	1	4 to 8
0.021 to 0.040	1	8 to 16
0.041 to 0.080	2	16 to 24
0.081 to 0.120	3	24 to 34
0.120 to 0.160	4	34 to 50
0.160 to 0.180	5	50 to 58
0.180 to 0.200	6	58 to 64

Polishing

After the celluloid sheets have been dried they have warped more or less and have to be straightened. As the celluloid sheets are generally sold to the trade polished, the two operations of straightening and polishing are carried out in the same hydraulic press. The press used is of very heavy construction and generally has two rams above which are twelve semi-steel plates which are supported so as to leave an opening of about 2½ in. between the plates. Each plate is cored and connected to the main pipes distributing steam and water. The dimensions of the plates are generally 56 x 25 in. and the maximum gage pressure used during the polishing is 3,500 lb. per square inch.

The polishing is done by heating under pressure the sheets placed between polished plates; after cooling the surface of the sheets will have a perfectly polished surface.

The polishing plates used have to be of first quality, and it seems that the best are made in Germany. During the World War every factory experienced great difficulty in getting a supply of good polishing plates. These plates are generally made of a steel sheet on each side of which a layer of nickel is rolled while the metal is hot. The rolling process is kept on until the metals are cold; then the plates are submitted to a special polishing process which will give a perfect finished surface. Different alloy compositions have been tried from time to time, but only pure nickel keeps this surface perfect for a long period and after the plates have shown wear marks they can be refinished.

The polishing operation is as follows: The cleaned celluloid sheets are placed between nickel polishing plates and two to eight sheets are then piled up, the number varying with the thickness of the celluloid sheets and the opening between two press plates. This is called a set; each set is placed between heavy pads of cotton sheets which are supported by steel sheets. The press, which has been heated during the laying operation to around 85 deg. C., is then filled and low pressure—that is, about 500 lb. per square inch—is applied during the heating period, which lasts from 1½ to 5 minutes, according to the thickness of the celluloid sheets to be polished. Then cold water is sent through the press, the pressure being kept around 3,000 to 3,500 lb. After the cooling operation, which takes from 15 to 45 minutes, the pressure is shut off and the sheets are taken out. In Europe the polishing presses are of the same construction but stronger so as to resist pressures up to 6,000 lb. per square inch.

After polishing, the celluloid sheets are trimmed to 50 x 21 in. generally and are then stored in unheated rooms until they are sold and shipped away.

Manufacture of Rods and Tubes

Celluloid rods can be made by two ways—by cutting or by stuffing. Generally the cutting method is used for shell and mottled designs, the stuffing process being used for uniformly colored rods. The cutting of the rods is done with the sheeting machine employed to cut sheets, the knife being replaced by a cross-feed screw supporting a tool head in which are inserted special steel cutters placed at different heights and on the side of which are small individual angle knives which edge the stock left after the rods have been cut. This method of cutting rods gives the best of results, the only disadvantage being the great quantity of scrap produced, this varying, with the gage of the rods cut, from 40 to 50 per cent. The loss of solvent during the operation reaches 5 to 8 per cent, and the solvent left in the rods after cutting varies from 8 to 10 per cent. Another method for cutting rods is to use special cylindrical presses in which the celluloid paste is pressed on a steel axle which is placed in the center. After cooling, the block is transferred to a specially constructed lathe on the front of which a cutter moves, thus cutting an endless rod.

The stuffing of rods is done on specially constructed hydraulic presses which are composed of a cylindrical cast-iron chamber which can be heated or cooled. (See Fig. 6.) In this chamber is placed the specially rolled paste, which is pushed through a die by a hydraulic ram working at a pressure varying from 500 to 3,000 lb. per square inch. The heating and pressure, combined with the density of the paste, are the factors regulating the production of a perfect rod. The heating has to be perfectly controlled around 75 deg. C., as above this temperature decomposition of the celluloid paste can take place and frequently disastrous accidents are reported which are generally due to the carelessness of the operator. In some factories the hydraulic stuffers are replaced by mechanical ones which are of the same construction as the mechanical straining machine described before, but the cylinders are smaller, being generally from 4 to 6 in. in diameter. These mechanical stuffers require 10-hp. motors and are as efficient as the hydraulic ones, although the density of the paste to be stuffed has to be varied.

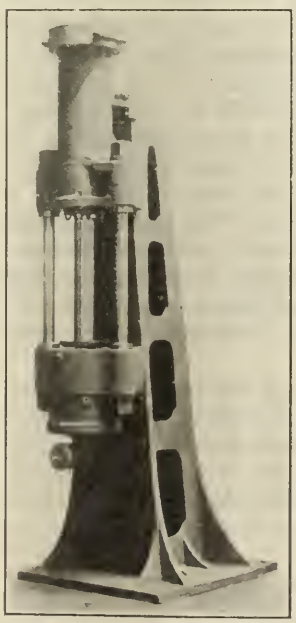

FIG. 6. EXTRUDING PRESS FOR RODS AND TUBES

The two machines just described can also be used for making tubes, and in this case a special die having a pin in the center is used. As to the production, this varies with the dimensions of the rods and tubes to be made and also with the capacity of the cylinder. As an indication, from 7 to 9 lb. of 0.100-in. gage rods or tubes can be made per hour using a machine having a cylinder diameter of 4 in.

Scrap Utilization

All scrap made in the factory, together with that coming from the manufacturers of novelties, is made into celluloid. The scrap coming directly from the factory is sorted by colors and thicknesses, and mixed as soon as possible. Dry scrap has to be washed and submitted to a cleaning and sorting process before mixing.

The scrap can be mixed in boxes similar to those described for the mixing of cellulose nitrate. Generally 3 to 5 per cent of camphor and 20 to 35 per cent of denatured alcohol is required according to the scrap used. After standing for a period varying from 3 to 6 days the scrap paste is cut and, after a slight rolling, is filtered. This scrap paste can be used alone, but it is generally mixed in different proportions with cellulose nitrate paste to make a celluloid block.

So as to reduce the quantity of alcohol and the time of mixing, most of the celluloid plants use large specially constructed tumblers in which the scrap and camphor alcohol solution are kept in motion for about 1 hour. This method reduces the time of the operation.

Camphor Substitutes and Synthetic Camphor

True celluloid is made with natural camphor which has been refined. Sometimes, when camphor prices are too high, as was the case during the war, substitutes have to be used. The number of substitutes which can be used is limited. Acetanilide, methylacetanilide, tricresylphosphate, triphenylphosphate, triacetine, etc., have all been tried. Acetanilide is a poor solvent for cellulose nitrate and above 10 per cent in mixtures with camphor gives a brittle celluloid which changes color with time. Methylacetanilide, having a very low melting point, produces a celluloid which is entirely too soft and discolors quickly. Generally the same can be said of the other substitutes; but nevertheless during the war great quantities of triphenylphosphate were used and some absolutely camphorless celluloid of excellent quality was manufactured which has kept perfectly up to this time. To obtain this celluloid specially purified triphenylphosphate was employed in connection with a specially prepared cellulose nitrate. By modifying the manufacturing process a little very good results were obtained, and the only contradictory fact observed was that the celluloid produced was harder than celluloid made with camphor, but this was probably due to the grade of cellulose nitrate used.

With the drop in price of Japanese camphor, the use of these substitutes (which are generally higher than camphor in price), has been discontinued, much to the satisfaction of manufacturers using outside celluloid scrap, as a great quantity of celluloid made with technically pure triphenylphosphate has given trouble on account of discoloration.

The subject of synthetic camphor requires only brief consideration. When properly prepared, synthetic camphor is practically identical with the natural product. Its manufacture is not a recent development, however. As far back as the Russo-Japanese war, when camphor was unobtainable in Europe, the writer was using synthetic camphor made by the Ampere Company working the Thurlow process, with very good results. Abroad, the manufacture of synthetic camphor has become active again due to the high price of camphor there. The resumption of the domestic industry depends upon several factors: The tariff; the price of camphor maintained by the monopoly; the price of turpentine. At this writing synthetic camphor of very good quality from abroad sells at the present price of Japanese refined camphor.

Chemical Control

The chemical control of a celluloid factory is quite a large undertaking, for if each step of the process is not regulated trouble will arise. Not only must the nitration, acid recovery, washing and bleaching operation be controlled very carefully, but the solvent, camphor and camphor substitutes, dyes and pigments must also be tested. In spite of this, almost every day the laboratory will receive some sample of stock which has given trouble during manufacture. Furthermore, there is always research work to be done on methods for improving the finished celluloid. In fact, every day something new has to be learned and the chemist is responsible in large measure for the success or failure of the manufacturing processes.

The writer desires to express his indebtedness to the following firms for the illustrations of celluloid machinery: Farrel Foundry & Machine Co. and the Allen Machine Co.

Corrosion of Underground Pipes*

In certain sections a very serious condition exists in connection with underground pipe systems, owing to the corrosive action of the soil upon the iron of which the pipe is made. The loss from this cause is so large that the Bureau of Standards has recently undertaken an extensive investigation of the subject with particular reference to the corrosive action of soils on gas and water mains.

In this investigation the bureau has the co-operation of the Bureau of Soils of the Department of Agriculture, the pipe manufacturers and the public utility companies through the research sub-committee of the American Committee on Electrolysis. Forty locations have been selected representing the different kinds of soils to be found throughout the United States, and at each locality a number of samples of every kind of iron and steel pipe in commercial use will be buried. Some of these samples will be uncovered from time to time to determine the rate of corrosion. Complete data on the physical and chemical properties of the soil and the pipes will be obtained and extensive laboratory experiments will be conducted to determine the effects of variations and individual characteristics of both soils and pipe materials. Some tests of representative pipe coatings will also be undertaken.

The results of the tests should be of great value in determining the importance of soil corrosion and in selecting the kind of pipe best suited for use in any particular soil. It is expected that considerable data as to the relative rates of corrosion of the different kinds of pipe in the soils under observation will be obtained within 2 or 3 years, but the investigation will probably continue over a period of 8 or 10 years.

The Manufacture of Chromium Ball-Bearing Steel in the Heroult Furnace

A Description of Melting and Processing of Electric Ball-Bearing Steel, With a View of the Most Serious Defects in This Class of Material—Recommended Practice for the Elimination and Control of These Defects

By F. T. SISCO
Metallurgist

THE manufacture of electric high-carbon chromium ball-bearing steel in 6- to 8-ton lots has until recently been accompanied by the difficulty of producing a product which is free from surface seams and internal hair lines. The former defect, while serious, may be eliminated by proper treatment during melting and processing. The latter, which seems to be an oxidation defect not got rid of in melting, persists through all further working of the steel and appears finally as a failure in the hardened ball or race.

Previous to 1914 the finest carbon chromium ball and ball race steel was imported from Germany in the form of billets; completed manufacture was in this country. One large firm, at least, manufacturing ball bearings and ball races owes its reputation to this German steel. Excellent ball steel has been made by the crucible process, some being produced by this method of manufacture to this day. However, the manufacture of good ball steel in common with other alloy steels should be the feature of the electric furnace, which theoretically should produce a perfect ball steel from a cheap base material. This statement should not be construed to mean that no good ball steel is as yet made in the electric furnace. There are many manufacturers that are producing an excellent steel for this purpose, but the fact is they are not doing it consistently. Even those plants making a specialty of this grade of steel occasionally tap heats of which 20 per cent, 50 per cent or even all must be relegated to the scrap pile.

It is the object of the author to describe in the lines that follow the practice developed at an electric steel plant, a practice that was the result of four years' study of this steel and by which a more uniform and better product was obtained.

The three defects that seem to be especially common and prominent in carbon chromium steels are segregation, surface defects and internal defects. The first two are more or less under the control of the melting, rolling, chipping and inspection departments. The third presents a difficulty unique in that it is apparently caused by the raw materials charged into the furnace and not subsequently eliminated.

Carbon chromium steel for ball bearings and ball races is made of only one grade of material, the carbon ranging from 0.90 to 1.20 per cent, the manganese 0.20 to 0.50 per cent, the chromium 1.10 to 1.75 per cent. Silicon is generally under 0.30 per cent and phosphorus and sulphur low. The most common analysis for this steel is carbon 1.00 to 1.15 per cent, manganese 0.25 to 0.45 per cent, chromium 1.35 to 1.65 per cent, silicon 0.15 to 0.25 per cent and phosphorus and sulphur below 0.025 per cent. The steel owes its properties to the presence of double carbides of iron and chromium, which confer great hardness on the metal, a hardness which is not accompanied by as much brittleness as the hardness of carbon alone. On the behavior of these carbides depends the successful annealing and subsequent hardening of the steel. When properly hardened the steel is martensitic probably with a little troostite present, especially if slightly drawn, and in breaking presents a fracture that is very close grained and silky, not unlike the fracture of hardened high-speed steel.

Melting

The best melting practice[1] for the manufacture of this steel is melting with partial oxidation. Theoretically, in the Heroult furnace complete deoxidation is possible no matter how badly the molten bath is contaminated with oxides and gases. Practically, however, due principally to insufficient knowledge of the fundamental principles of deoxidation, and especially since the molten bath must be very thoroughly deoxidized to make good ball steel, melting down to avoid oxidation as much as possible is preferable.

The scrap used should be selected, free from excessive rust and scale and not exceeding 0.05 per cent sulphur and phosphorus. A mixture of ball steel crop ends, open-hearth scrap such as billet and bloom crops, boiler plate, etc., makes an excellent base. For a 15,000-lb. heat 600 to 800 lb. of limestone is charged on the bottom of the furnace, followed by the scrap. It is sometimes advisable, when considerable low-carbon scrap is charged, to introduce a few hundred pounds of low-phosphorus pig iron down toward the bottom of the charge. Care should be used to avoid too high a temperature during melting, as the selective oxidation of the phosphorus depends almost wholly on this factor. There will always be sufficient oxygen present in the scrap to permit the easy and complete elimination of all of this element. The cold charge may be melted down with high power until a fair-sized pool of molten metal is present around the electrodes. Complete melting of the charge is then hastened, and the temperature kept low, by pushing into the pool, by means of iron bars, the partly melted sticky mass of scrap clinging to the sides of the furnace.

When the charge is completely melted, a test sample is taken out and sent to the laboratory for immediate analysis of carbon, phosphorus, manganese and chromium. In case much chromium scrap was used in the charge, the slag may be viscous, especially if the chromium oxide, Cr_2O_3, is near 10 per cent. This slag can be thinned sufficiently by the addition of a little fluorspar.

[1]Many points in connection with the melting practice has been discussed in a previous article entitled "Deoxidation and Desulphurization in the Heroult Furnace," appearing in CHEM. & MET. ENG., vol. 26, No. 1, p. 17, Jan. 4, 1922.

In about 10 minutes the phosphorus result is reported, and if within specified limits the furnace is tilted slightly and the oxidizing slag removed by hand rabbling. The final portion of slag near the banks is easily removed by throwing a few shovelsful of lime on the metal and poling the now thick mass to the front by means of long green saplings introduced through each side door.

If the scrap was selected properly and if melting conditions were correct, the bath when melted will contain 0.50 to 0.75 per cent carbon, about 0.20 per cent manganese, chromium varying from a trace to 0.75 per cent, depending upon the amount of chromium scrap used, sulphur between 0.02 and 0.04 per cent and silicon and phosphorus below 0.025 per cent. The white slag is then immediately applied as described below. The presence of considerable carbon, some of the manganese and more than half of the chromium insures a metal in which oxides and dissolved gases cannot be present in large amounts.

When sufficient chromium scrap from the plant rolling mills and inspection sheds is available for a whole heat, the melting may be carried out quickly without oxidation. This method insures a more thoroughly sound and deoxidized steel than any other form of melting practice, but can be used only when scrap containing phosphorus well below the required percentage in the finished steel is used.

This rapid method consists essentially of melting a charge made up completely of ball steel scrap, and commencing the building up of the white slag as soon as there is molten metal present in the furnace. When this practice is used, the composition of the steel after melting will be carbon 0.85 to 1.00 per cent, manganese 0.20 to 40 per cent, chromium 1.10 to 1.30 per cent, silicon about 0.05 per cent and sulphur and phosphorus low. The phosphorus will be the same as or very slightly higher than the percentage in the scrap, as none is lost in melting. Even though this melting under a white slag produces quicker heats, more satisfactorily deoxidized heats in many cases, as well as a steel to which no alloy additions except a little ferrochromium need be made, however as a daily practice it is impractical on account of the scarcity of suitable scrap. It is often possible when melting and working large tonnages of chromium steel to collect enough plant scrap so that a series of white slag heats may be made, but due to the fact that chromium steel scrap, and other scrap for that matter, containing less than 0.02 per cent phosphorus is never available in large tonnages, the partial oxidation process above described is preferable. In no case should a complete oxidation in melting be tolerated for this grade of steel. This practice, so common in electric steel plants, consists essentially in melting down almost any kind of scrap with limestone and iron ore or roll scale, so that all of the carbon, silicon, phosphorus, manganese and chromium, if present, is oxidized and removed from the metal. This practice when applied to chromium steels produces almost without exception a low-grade product. High-carbon, high-chromium steel is perhaps one of the most sensitive of the alloy steeels made in the Heroult furnace, and one of the most difficult to deoxidize completely.

In the case of most other steels it is not difficult to remove excessive oxide and gas contamination caused by melting with iron ore or roll scale; with chromium steel, however, as most of the trouble occurs between the time of the ferro-alloy addition and the pouring of the ingots, it is highly desirable to have a steel almost 100 per cent deoxidized before making the ferro-alloy addition.

Why it happens in many cases that a charge of ordinary scrap melted low in carbon, recarburized on the bath, apparently completely deoxidized by a good carbide slag will make an almost perfect heat of carbon tool steel on one hand, and why on the other hand the same practice will make a heat of chromium steel with thousands of microscopic hair-line seams, the author will not attempt to explain. It is practically proved that the addition of ferrochromium is largely responsible.

Experiments, in which ingots were made by different melting practices and followed through all further processing, proved conclusively that melting to retain a portion of the carbon, manganese and chromium produced uniformly a better product, more nearly free from surface seams and internal hair-lines than melting with complete removal of these elements followed by recarburization on the bare metal.

Deoxidation

The deoxidation is accomplished with the customary white or carbide slag. This slag is composed of lime, crushed coke and fluorspar in the proportion of 6 to 2 to 1 and is mixed before being added to the furnace. Best practice with a 6-ton Heroult furnace requires 1 lb. of slag to each 15 or 20 lb. of metal. Under high power

FIG. 1. TAPPING A HEAT OF CARBON CHROMIUM BALL-BEARING STEEL

the slag should be in condition and should carry 1 to 3 per cent calcium carbide within 45 minutes after being applied. By luting the furnace doors to exclude atmospheric air as much as possible 30 minutes further should suffice for an almost complete deoxidation of the bath. A sample for analysis is now quickly taken and all of the ferrochromium and ferromanganese added. Five minutes suffices for the melting of the alloys, after which the bath is well stirred through each door. Further slag additions are now made if necessary and the furnace is again sealed until carbon results are obtained from the laboratory. The results of the analysis will probably show that some recarburization is necessary; addition of carbon is made in the form of washed metal

or low-phosphorus pig iron. When this is melted down, a few shovelsful of slag are scattered on the bath and the furnace is again sealed. If the bath appears too hot, the power may be reduced slightly for the remainder of the heat. At least 1 hour should be given to complete the deoxidation after all alloy additions are made.

Results of continued investigations have shown that this period is absolutely necessary if surface seams are to be avoided. It is also advisable to keep the metal very hot during the deoxidation period, a bath temperature of 3,200 deg. F. (estimated) being the best. If, after being under the white slag for 2½ hours, a metal test is "quiet" with no perceptible bulging or sparking, the ferrosilicon is added and the bath stirred as soon as the alloy is melted. Doors are now closed tight and the power is shut off completely for 5 minutes or more or until the metal cools to tapping temperature (3,000 to 3,050 deg. F.). If a heat test and if slag test show temperature and slag conditions correct, the ladle is placed in position and the heat tapped. (See Fig. 1.)

Tapping and Pouring

In tapping, the slag should be held back completely if possible. On some of the older furnaces it is necessary to use a skimmer for this purpose. More recent types have a tap hole instead of the wider spout, an arrangement that permits the rapid tilting of the furnace until the slag line is above the tap hole. In no case should metal and slag be tapped together, permitting the mechanical intermixing of the two in the ladle. As soon as the ladle is filled, five or six large shovelsful of lime are thrown on top and the ladle is held 5 or 10 minutes before pouring. Holding the heat in the ladle during this period is an extra precaution with chromium steels, as it permits the last traces of oxides and entrapped gases to rise to the surface.

The additional wear on furnace and ladle linings by deoxidizing and by tapping exceptionally hot heats is more than justified by reduction in segregation and oxidation defects.

FIG. 2. POURING A HEAT OF CARBON CHROMIUM BALL-BEARING STEEL

With ball-bearing steel it is necessary that every precaution be taken to prevent oxidation or contamination of the metal after it leaves the furnace. Clay ladle washes commonly used should be avoided, as the thin clay coating invariably spalls off and some of it becomes entrapped in the metal.

The most common ingot size for 6-ton heats is 9 x 9 in. The molds may be either solid or split, the former undoubtedly giving the better results. The molds are slightly round cornered, are 9 x 9 in. at the top and taper to 8 x 8 in. at the bottom. Stools accommodate two molds and are so designed that the connection between mold and stool is sufficiently tight that packing is unnecessary. The top is offset in such a way that the sink-head sets 2 in. down into the mold. (See Fig. 2.) The clay sink-heads are dried and warmed over gas burners before being placed on the mold. To prevent sticking, the inside of the mold is slurred with a mixture of hot tar and kerosene oil applied with a long-handled brush. Ingot markers containing the heat and

*Analysis of scrap approximate.

ingot number are placed in the top of the ingot as soon as poured.

Pouring should be as rapid as possible and through a 1¼-in. nozzle; the temperature at the start should be about 2,950 to 3,000 deg. F. Extensive pouring tests covering months have shown that direct pouring when handled correctly is by far the best for chromium steels. After trying all possible forms of box and pot pouring, these were finally abandoned in favor of the direct-poured practice. This practice at an initial temperature of 2,950 deg. F. leaves, after pouring fourteen to seventeen ingots, a slight skull of 50 or 100 lb. in the ladle.

The ingots are covered with a mixture of lime and powdered coke and no special precautions are taken to eliminate pipe. The temperature and pouring practice just described practically eliminates possibility of secondary pipe and throws the main pipe and all segregation well up into the sink-head, where it is cropped and scrapped.

The ingots are stripped 90 minutes after pouring and placed in a pit, where they are covered with ashes for 36 to 48 hours. Table I shows the chemical history of a heat of chromium ball steel melted with partial oxidation; Table II shows the same kind of steel, the charge being wholly chromium steel scrap and melting being under a white slag.

Processing

The ingots are chipped, if necessary, to remove any pits, pock marks or metal shots. A little chipping of the ingots will frequently save much chipping labor after roughing to billets. The ingots are then reheated for rolling. It is a characteristic of chromium ball steel that with the exception of internal hair-lines most defects if present will be found on or very close to the surface. For this reason the heating for initial rolling should be controlled so as to produce free and heavy scaling. If forging billets are made, rolling is direct, 10 per cent top discard and about 5 per cent bottom discard being scrapped. When large bars (2 to 4 in.) are made, and this constitutes the most important and the bulk of the chromium steel business, two procedures are followed—direct rolling and roughing and re-rolling. The latter method unquestionably produces the best result and will be described in detail. For the large size rounds (2 to 4 in.) the ingots are heated to a free scaling temperature and roughed to 4- to 6-in. gothic billets. The top, 3 or 4 in. below the sink-head, is nicked on all sides by the hot saw and the bottom discard of about 5 per cent completely removed by the saw. The billets are rolled onto the hot bed and placed in close contact with one another, being covered in cold weather with a layer of lime or ashes. Finishing temperatures, while not so important in the roughing, should not be too high.

After cooling, the sink-head end of the billet is removed by breaking and the fracture examined for pipe. In case this appears, the billet is nicked back 6 in. with an acetylene torch and again fractured, which process is repeated until there is no evidence of pipe. The top discard in this class of steel should never be below 10 per cent and preferably should approach 15 per cent.

After fracturing, the billets are pickled and chipped clean from any seams or flaws. If melting was correctly accomplished, chipping should be slight. The billets are then reheated and rolled to finished size, excessive scaling being prohibited in the finished rolling, which is done with careful attention to surface appearance and finishing temperature, the latter being near the critical range, 1,375 to 1,400 deg. F.

At this point both top and bottom discard from the finished bars representing the first, middle and last ingots of each heat are sent to the laboratory and analyzed for carbon, manganese and chromium. If the maximum variation among the six tests on the heat does not exceed 0.05 per cent on each element, segregation is considered absent. By the method above outlined, fracturing top discard on roughed billets and re-rolling, segregation is practically impossible with good melting and pouring practice.

The bars are given a close file inspection for seams

and one bar from each heat is selected for hair-line tests. The inspected bars are then annealed. Consumers of this grade of steel require that chromium steel bars be soft enough for satisfactory work in automatic machines—that is, 170 Brinell or below—and that bars pass rigid hardening tests. To fulfill both requirements means that in annealing, all cementite, both excess and combined with the pearlite, must be spheroidized. This is very essential if the complete absorption in hardening, which is necessary for a uniform martensitic structure, is to be attained.

All bars above 1 in. in size must be normalized as well as annealed. To this end and to prevent decarburization the bars are packed in heavy walled cast-iron pipes, 14 in. in diameter and 16 ft. long. Any spaces not occupied by the steel are filled with a mixture of charcoal and ashes and the ends sealed with brick and fireclay.

To facilitate rapid and economical handling during normalizing and annealing, a car type furnace is used, with doors at both ends. Two cars are provided, being fastened together. Car No. 1, being loaded, is pulled into the furnace, the doors are closed and sealed and the furnace is fired. The mass is heated as rapidly as possible to 1,725 to 1,750 deg. F. and then held at this temperature for 12 hours. While at this temperature car No. 2 is loaded. After the 12 hours' heating at normalizing temperature the furnace doors are opened, car No. 1 is drawn out, No. 2 being drawn in at the same time. After car No. 2 is held at temperature (1,725 to 1,750 deg. F.) for the specified time, it is withdrawn, car No. 1 being drawn in simultaneously and the open furnace now cooled rapidly to 900 deg. F. or slightly below. The doors are then closed and the first lot is now heated at the rate of 20 deg. per hour to 1,400 to 1,420 deg. and held at this temperature for 24 hours. Cooling is at the rate of 10 deg. per hour down to 800 deg. F., when the doors are opened and car No. 1 is withdrawn. While this charge is cooling and the pipes are being unloaded and recharged, car No. 2 is being annealed at 1,400 to 1,420 deg. F. for 24 hours, with subsequent slow cooling as in the case of car No. 1.

This method of annealing insures complete spheroidizing of all the carbide and produces a steel which will range from 155 to 165 Brinell.

After unloading, the bars are run through a machine that straightens and imparts an oiled polish to the surface. A disk $\frac{3}{8}$ in. thick is cut from every third bar for hardening tests. The steel is now ready for shipment.

Rough Turning Chromium Bearing Steel

An extensive study of comparative costs and quality of product was made between the practice above described and the following. Knowing that the majority of defects in chromium steel (aside from hair-line seams, which will be discussed later) are surface seams, another method was tried to eliminate these. The ingots were chipped, reheated and rolled to finished size direct in the case of the larger bars, roughed to gothic billets and finish rolled to size in the smaller bars. In all cases finish rolling was $\frac{1}{16}$ in. full. The bars were open annealed, straightened and rough turned to size. Inspection was after rough turning. This practice eliminated pickling, much of the chipping and the extra pipe cost in annealing. The product was undoubtedly better in appearance, was somewhat freer from seams than the regular product and on the basis of cost studies could be made just as cheaply as the regular product. The only objection to regularly rough turning chromium steel is the large amount and excessive cost of the equipment necessary to handle a considerable tonnage in this manner. In a plant where this equipment was available this practice would be preferred as producing the best product possible.

Hardening Tests

These tests are made to determine the correctness of the normalizing and annealing operation and to determine whether all of the cementite is completely spheroidized. The disks cut from the finished bars are placed in a small gas-fired or electric heat-treating furnace and brought to 1,435 to 1,450 deg. F. and held at this temperature for 20 minutes. They are then withdrawn and immediately quenched in cold water. With a sledge the disks are broken in half and the fracture of the hardened steel is examined. A perfectly annealed piece results in a fracture that is very fine grained, silky and silvery in appearance. Dark streaks or spots due to undissolved carbides should be entirely absent.

Tests for Hair-Line Seams

One annealed bar about 6 ft. long is picked from each heat, straightened and rough turned to remove scale. It is then placed in a lathe, 6-in. sections being turned down so that each section is progressively $\frac{1}{4}$ in. smaller in diameter than the preceding. A $3\frac{1}{2}$-in. round bar 6 ft. long will have twelve sections ranging from $3\frac{1}{2}$ in. down to $\frac{3}{4}$ in. diameter, exposing successively the whole bar from center to surface. With a reading glass that magnifies about five diameters the bar is closely examined and the number of hair-line seams on each section counted.

The Hair-Line

The following peculiarities and characteristics of the hair-line seam have been noted by the author in the past 5 years. This defect is a very small, almost microscopic crack in the bar, always running in the direction of rolling. It is undoubtedly an elongated hole caused by very small particles of gas being entrapped in the steel. It may be present in any part of the bar and is apparently well distributed throughout the mass of metal. It is a spot of weakness and, due to the drastic hardening treatment accorded to this grade of steel, will form a spot from which ultimate failure of the hardened ball or ball race will originate. It is a defect that is found in appreciable amounts in this grade of material only, it being especially evident when the chromium content is around 1.50 per cent and the carbon 1.00 per cent. The best melting practice will reduce the number of hair-lines present, but will not eliminate them entirely.

Given a uniform melting practice, uniform conditions of rolling and annealing, the hair-line seam will appear in steel in which high-carbon (6 to 8 per cent) ferrochromium was used, but will be almost entirely absent in steel made from 2 per cent carbon ferrochromium. A heat made from ball steel scrap entirely, scrap consisting of billet crop ends and bars rejected on account of seams and hair-lines and melted under a white slag without oxidation, will be almost free from this defect. Some shipments of 6 per cent carbon ferrochromium produce a steel badly contaminated with hair-line seams, while other shipments of the same class of alloy will produce

a steel with few of these defects. Steels made from 6 per cent carbon ferrochromium purchased in 1916 and 1917 were singularly free from hair-lines, while steels made from the same alloy made under pressure of war conditions in 1918 and 1919 were badly contaminated.

From these facts it is probable that in the ferrochromium lies the origin of the hair-line seam. Melting with as little oxidation as possible in the presence of a strongly carbide slag and adding the ferrochromium as early in the heat as possible will help to reduce the number of the hair-line seams.

While the origin of the hair-line has been accounted for by a well-developed theory, lack of conclusive evidence to substantiate this theory makes it unwise to publish it at this time.

Another interesting fact in connection with chromium steel of the above composition: The author had noted for some time the peculiarity of the relative solubility of chromium steels in nitric acid. Treatment accorded to all ladle test samples of chromium-bearing steel was as follows: The small test ingot[2] was stripped from the mold as soon as solid and buried in a bucket of lime for 45 minutes. It was then quenched in water and drilled at slow speed with a high-speed drill. The drillings were screened and 5 g. of the steel that passed 20 mesh and was retained on 40 mesh was digested just below the boiling point with 100 c.c. of dilute nitric acid, sp.gr. 1.16. Some of the steels dissolved completely in 15 or 20 minutes, others dissolved much more slowly, and still others, notably white slag heats, were practically insoluble. In conjunction with the inspection department an attempt was made to correlate these phenomena with the quality of the steels. In every case it was found that rejections were the highest on those heats whose drillings dissolved most easily in nitric acid, while the heats whose drillings dissolved with great difficulty or were practically insoluble were free from surface seams and internal hair-lines. By means of this test the chief inspector was prepared several days in advance and had an accurate idea of the quality of the steel he was to pass upon.

The relation between solubility and hair-lines was especially noticeable. After a few trials it was possible to foretell with fair accuracy the percentage of rejections on this account. The accuracy of the solubility test, however, is absolutely dependent upon the degree of hardness of the test-piece drilled. It is comparative only and fails utterly unless all ladle test-pieces have been similarly treated and unless all are fairly hard. The least softening of the steel affects its solubility very markedly and comparisons are then impossible.

Deoxidizing Ball-Bearing Steel With Ferrotitanium and Ferrovanadium

Several heats of this steel were made using ferrotitanium as an additional deoxidizing agent. In some heats the titanium alloy was added to the furnace after the ferrosilicon and just before tap. Two to three pounds of the alloy was used for each ton of steel and the melt was well stirred after the addition. In other cases the alloy was thrown into the ladle as soon as the bottom was covered with metal. In both cases the steel was held in the ladle 5 to 10 minutes before pouring.

A few heats to which sufficient ferrovanadium was added to the metal to give a vanadium content of 0.03 to 0.05 per cent were made and processed for comparative tests. No departures were made from the usual practice in processing from the ingot to the finished bar. Inspection and hair-line tests showed that both alloys produced a steel slightly superior to the regular product. It is questionable, however, whether the slightly better results were justified by the increased cost, especially in the case of ferrovanadium.

[2]Standard test No. 1; an ingot 1½ x 1½ x 8 in. high, top flared to act as sink-head. See p. 8, U. S. Steel Corporation pamphlet "Methods for the Commercial Sampling and Analysis of Plain Steels."

Summary

From the results of 5 years' experience on high-carbon, high-chromium ball steel the following was adopted as the practice productive of the most satisfactory steel at the lowest cost:

Melt selected scrap with partial oxidation to eliminate phosphorus and to retain most of the carbon, manganese and chromium. Deoxidize with a strongly carbide slag, excluding atmospheric air from the furnace as much as possible and adding the ferrochromium as soon as the metal is deoxidized and the slag in good shape. Allow at least 1 hour for further and complete deoxidation after the alloy has been added. Deoxidize on a very hot bath and tap metal at about 3,000 deg. F. or a little above, holding 5 to 10 minutes in the ladle before pouring. Bury ingots for at least 36 hours in ashes.

Chip ingots and reheat, permitting them to scale freely. Rough to a gothic billet and fracture to expose possible pipe. Pickle, chip and reheat for final rolling. Roll to finished size with particular attention to finishing temperature. Inspect for seams, normalize, air cool and anneal for 24 hours at 1,400 to 1,420 deg. F. with slow furnace cooling. Machine straighten. Adherence to this practice, provided a clean ferrochromium is used, will produce a product free from surface defects and with a minimum of hair-lines.

Charleston, W. Va.

Effect of Upper Silesian Plebiscite on Chemical and Metallurgical Industries

The *Chemisch-Technische Industrie* estimates that the result of the partition of the plebiscite area in Upper Silesia is to give Poland nearly 76 per cent of the coal production, 96.9 per cent of the iron ore production, 81.9 per cent of the zinc ore, 70.9 per cent of the lead ore and 26 per cent of the sulphur ore. Of the production of coke 50.6 per cent and of coke byproducts 50.2 per cent goes to Poland. The zinc and zinc byproducts industries and the lead and lead byproducts industries fall entirely into the hands of Poland, with 43.8 per cent of the petroleum-refining industry and 75.6 per cent of the coal-distillation industry. Poland also obtains the whole sulphuric acid industry.

Preparation of Synthetic Organic Chemicals at Rochester

The address on "The Preparation of Synthetic Organic Chemicals at Rochester" presented by Drs. C. E. K. Mees and H. T. Clarke before the Society of Chemical Industry, Montreal, Aug. 31, 1921, has been published in the form of an illustrated booklet, copies of which are obtainable upon request from the Eastman Kodak Co.

As a natural consequence of the attempt to produce a great variety of highly specialized products, methods for carrying out organic syntheses were developed which should be of interest to organic research workers in general. Typical set-ups are illustrated and many novel features explained.

Manufacture of Phosphoric Acid and Phosphates

General Treatise on the Acid-Decomposition Process in Industrial Production—Dissolving the Raw Ore—Removal of Impurities—Monocalcium and Dicalcium Phosphates—Concentration and Grading of the Salts—Production of Sodium Salts From Phosphoric Acid

By JACOB T. MECKSTROTH
Consulting Engineer, Columbus, Ohio

THE manufacture of phosphoric acid and phosphate salts may be divided into two general processes. One is called the pyrolytic or volatilization, the other the acid-decomposition process.

The pyrolytic or volatilization process is at present used only in the manufacture of the highest grade of the so-called chemically pure phosphoric acid. This process has not yet been developed to the commercial efficiency of producing an acid at a cost to compete favorably with the acid-decomposition process. There is, however, no doubt that the day is not far distant when the pyrolytic or volatilization process, as described by Waggaman and Wagner in the *Journal of Industrial and Engineering Chemistry* for May, 1918, and reported by Waggaman and Turley in the *Journal of Industrial and Engineering Chemistry*, vol. 12, 1920, p. 646, and in CHEMICAL & METALLURGICAL ENGINEERING, vol. 23, p. 1057, 1920, will become a commercial possibility and a strong competitor to the acid-decomposition processes.[1]

Acid-Decomposition Process

The process of decomposition, by means of 60 to 66 deg. Bé. sulphuric acid, is today the best developed and commercially successful, yet it is far from being satisfactory. The larger proportion of the acid is manufactured from phosphate rock, a tricalcium phosphate, with an admixture of silica and fluorspar, often called apatite or phosphorite. In the United States the important beds or deposits of this rock are found in Tennessee, Kentucky, Florida, South Carolina, Idaho and Montana. It is generally sold or purchased on a guaranteed basis of 75 to 80 per cent tricalcium phosphate, $Ca_3(PO_4)_2$, and its color varies from blue-green or gray to red-brown. The Tennessee and Kentucky rock has a color varying from blue to brown and has generally a higher percentage of iron and aluminum than the Florida, Idaho or Montana rock. The blue grade is usually lower in iron and aluminum than the brown grades, but is lower in the P_2O_5 content.

The Idaho and Montana deposits are being developed at the present time and are considered equal to if not actually better than either the Tennessee or Florida grade. On account of location and unknown quantity these deposits have not received the attention to which they are entitled and which they should receive. Large sums of money are being expended to utilize both the sulphuric acid from the smelter industry and the rock of the Montana and Idaho regions.

The rock deposits are frequently purchased outright by the manufacturer, although often concessional rights for a definite tonnage of definite quality are contracted for, and sometimes the rock is bought as run of mine and shipped to the plant where the grinding is done. The rock is mined by removing the overlying earth, separating the high grade by hand picking, washing, grinding and loading it in cars of approximately 40 tons capacity, to be transferred to the plant for its decomposition, purification and refining.

The disintegration of the rock begins with the mixing of definite quantities of water and acid or a weak acid with a weighed quantity of the ground rock. The following reaction takes place:

$$Ca_3(PO_4)_2 + 3H_2SO_4 = 2H_3PO_4 \text{ (soluble)} + 3CaSO_4 \text{ (insoluble)} \quad (1)$$

Remaining behind with the calcium sulphate in treatment of the apatite with sulphuric acid are impurities natural to apatite such as $AlPO_4$, $FePO_4$, unconverted CaF_2, SiO_2, etc. The H_3PO_4 filtrate carries with it as impurities more or less of the $AlPO_4$ and $FePO_4$, rendered soluble by the chemical action of the sulphuric acid. There is also some HF in the H_3PO_4.

During the mixing considerable heat is developed which may be controlled by the process of mixing or by the size of the mixes made. The mixing is best done in a lead or acid-resistant brick-lined tank of appropriate size. The agitation required during the mixing is such that mechanical stirring devices must be provided. Air agitation is quite expensive and unless the bath is heated is not to be recommended. Air cools the mixture, prevents efficient reaction and is often detrimental to the separation of the liquid from the solids. Ninety to 95 per cent of the reaction is complete in 1 hour after the last of the ingredients has been added —that is, if proper proportions are used.

Removal of Impurities

The removal of the insoluble and soluble impurities, consisting of the calcium sulphate, silica, as well as the compounds of iron and aluminum, fluorine, arsenic and lead, constitutes the problem of the phosphoric acid manufacturer.

The procedures for removing the various impurities differ with different manufacturers. It is possible to combine the removal of some of these impurities in one operation, and in order to decrease the number of processes it might be mentioned that the arsenic and any lead which may be present can be precipitated by treating the decomposition mixture with hydrogen sulphide gas. This leaves the insoluble arsenic sulphide, lead sulphide, calcium sulphate and silica, which may be separated or filtered from the soluble acid and impurities in one operation. By means of the counter-current decantation system or by means of filter presses, the insoluble calcium sulphate and silica may first be separated and the resultant liquid acid treated for the removal of the arsenic, which involves another filtering operation. The calcium sulphate is practically a worthless pro-

[1] See also CHEM. & MET. ENG., vol. 24, No. 11, March 16, 1921, p. 466, and vol. 25, No. 11, Sept. 14, 1921, p. 517.

ing a brown or chocolate or gray color. However, it may sometimes, if calcined, be used for the manufacture of ceramic products such as plaster, building blocks and tile.

After the removal of the calcium sulphate and silica, any weak liquid acid obtained in the process may be used in place of water for mixing in the decomposition tanks. By using a phosphoric acid of 16 to 18 deg. Bé. with 60 deg. sulphuric acid, an acid of 28 to 30 deg. Bé. can easily be obtained, which will contain from 37 to 40 per cent phosphoric acid depending upon conditions in the mixing. A liquid of almost any density and acidity may thus be obtained. It is economically impossible to remove all the soluble P_2O_5 from the insoluble calcium sulphate by washing. There is left, usually, from 1 to 2 per cent soluble, besides from 1 to 2½ per cent insoluble P_2O_5, calculated on a dry basis of the sulphate residue. From 1 to 2½ per cent of calcium sulphate will be held in solution by the liquid acid, part of which will, however, settle out upon standing.

Removal of Arsenic, Iron, Aluminum and Fluorine

To remove the soluble arsenic, treat the filtered liquid with hydrogen sulphide gas or a sulphide soluble in phosphoric acid. The latter will produce the hydrogen sulphide gas, which in turn will react with the arsenic in solution and form the insoluble arsenic sulphide. It is true that hydrogen sulphide is a dangerous and very objectionable chemical to use on account of its poisonous characteristics or properties. However, with the proper precautions, such as ventilating and aërating, all danger can be eliminated. After the arsenic has been completely precipitated or thrown out of solution the mixture or the acid liquid may be aërated by means of compressed air to remove the hydrogen sulphide gas before the filtration operation is to take place. The presence of hydrogen sulphide gas during any filtering or transferring operation is indeed objectionable even in small or dilute quantities. Hydrogen sulphide often produces colloidal sulphur or colloidal arsenic sulphide, which causes difficult filtration, but by having the mixture or liquid acid heated to not less than 40 to 65 deg. C. no trouble should be experienced. A clear liquid of straw color, practically free from arsenic and lead, is thus obtained.

The economical removal of the iron, aluminum and fluorine constitutes probably the most difficult problem of the phosphoric acid manufacturer. As in the case of the removal of calcium sulphate from the crude acid, a small percentage of these elements will remain in solution. Their removal may be accomplished in one treatment and one filtering operation. The phosphoric acid containing as impurities HF and iron and phosphates in solution can be purified by heating with carbonates or hydroxides of the alkalis or the alkaline earths. This brings about a precipitate, say if $CaCO_3$ is used, of the HF as CaF_2. The iron and aluminum salts also precipitate as $FePO_4$ and $AlPO_4$ respectively.

The insoluble iron and aluminum phosphate, the insoluble fluoride, together with some of the phosphate, which invariably combines or becomes insoluble during the specific treatment involved, may be removed either by the counter-current decantation process, or by using a wooden frame press, a box filter with pressure or vacuum or a rotary filter of the Oliver type. By adding sufficient amounts of alkali salts, all but the last traces of iron, aluminum and fluorine are removed from solution.

This insoluble material, after filtration and washing, is dried and sold to the fertilizer manufacturer. The dried product usually contains from 30 to 35 per cent of P_2O_5, depending on the care taken to perform the operation and the percentage of moisture it contains. The strength and specific gravity of the original crude acid and the temperature of the mixture during the operation are important factors to consider and need careful supervision and attention. A crude acid of 13 deg. Bé., for example, can be treated at ordinary temperature and good settling or filtration will result, whereas a crude acid of 25 to 28 deg. Bé. should be heated and very carefully treated to avoid any unnecessary loss and to produce a filtrable mixture.

The filtrate from this operation should have only a very small percentage of free acidity, but considerable phenolphthalein acidity or so-called total acidity. This liquid may be used in the production of a purified or edible phosphoric acid or dicalcium phosphate in the event a calcium alkali was used in the treatment. By treating the monocalcium phosphate solution with sulphuric acid free from iron, aluminum, arsenic and lead the insoluble calcium sulphate and phosphoric acid practically free of iron, aluminum, arsenic and lead are produced according to the following reaction:

$$CaH_4(PO_4)_2 + H_2SO_4 \rightarrow 2H_3PO_4 + CaSO_4 \qquad (2)$$

The calcium sulphate precipitated is a very white crystalline product, settles very readily and may be separated from the liquid acid by filter presses, by filter boxes, by the counter-current decantation system or by an acid-proof rotary filter. The white calcium sulphate after being thoroughly washed to remove the soluble phosphoric acid is either discarded or used in the manufacture of sulphated goods or materials. The dilute acid may be either marketed or concentrated to any desired strength and used in the manufacture or production of monocalcium phosphate or sold as concentrated liquid phosphoric acid.

Production of Dicalcium Phosphate

The monocalcium phosphate solution may be treated with milk of lime, hydrated lime or calcium carbonate, according to following reaction:

$$CaH_4(PO_4)_2 + Ca(OH)_2 \rightarrow 2CaHPO_4 + 2H_2O \qquad (3)$$

$$CaH_4(PO_4)_2 + CaCO_3 \rightarrow 2CaHPO_4 + H_2O + CO_2 \qquad (4)$$

In the production of the dicalcium phosphate, the concentration and temperature of both the milk of lime and acid solution play an important part in the process. As a general rule, the more dilute solution and higher temperatures give the higher grade product, both as to chemical and mechanical characteristics. There is little choice between using milk of lime or the hydrated lime except that the hydrated lime is the higher in price. The use of calcium carbonate, often called marble dust, is not recommended, on account of undecomposed carbonate resulting in the finished product.

The dicalcium phosphate is a white, crystalline product and may be separated by means of filter presses or boxes or settled in a Dorr thickener and filtered by a rotary type filter. Then it is dried by steam and with vacuum iron driers and ground to any mesh desired. This neutral product is invariably used by the manufacturer in the production of the mono-acid salt, according to the following reaction:

$$CaHPO_4 + H_3PO_4 \rightarrow CaH_4(PO_4)_2 \qquad (5)$$

The production of tricalcium phosphate may be accomplished by adding a solution of sodium phosphate to

a solution of calcium chloride in the presence of ammonia, washing the precipitate free from chlorides and ammonia, drying and grinding the product to a fine white powder. The ammonia and chloride may be recovered and again utilized.

As stated above, the weak purified liquid phosphoric acid, having a straw color, may be concentrated to a Baumé of 50 to 53 deg. and used in the manufacture of the mono-acid salt, according to reaction 5 or by the addition of ground, burnt lime or hydrated lime according to reactions as follows:

$$2H_3PO_4 + CaO \rightarrow CaH_4(PO_4)_2 + H_2O \qquad (6a)$$
$$2H_3PO_4 + Ca(OH)_2 \rightarrow CaH_4(PO_4)_2 + 2H_2O \qquad (6b)$$

Concentrating, Filtering, Grinding and Grading

During the concentration the acid invariably becomes dark in color, and common practice is to add oxidizing agents, such as chlorates or permanganates, until practically a water-white liquid is obtained. Care must be taken not to add the oxidizing agent in excess, on account of the presence of manganese, originally in the rock or in the permanganate used in the bleaching, which will cause the acid to turn a pink or a deep purple color. The concentration may be accomplished by passing the weak liquid acid over lead steam coils, through acid-resistant brick concentrators, or it may be concentrated by means of hot air-spraying systems.

The separation of small crystals of calcium sulphate from the hot solutions during the concentration process is troublesome, especially where lead steam coils are being used. These steam coils continually become coated with a hard sulphate scale, which must be removed by treating them with a solution in which the scale is soluble, by hammering or by picking the coils. This latter is a rather tedious and destructive method and contaminates the acid with lead. If an acid-resistant brick constructed concentrator is used, an occasional cleaning out is necessary, but no trouble with lead contamination is experienced.

Before the concentrated acid is to be mixed with the alkali or neutral salt to produce the mono-acid salt, the precipitated or insoluble calcium sulphate is removed by filtration. A small amount of calcium carbonate or dicalcium phosphate may be added before the filtering takes place. This will not only lower the percentage of soluble sulphate but will also cause the lead sulphate, if any is present, to be incorporated in the finely divided precipitate and be removed by filtration. The filtration may be accomplished with wooden frame filter presses, using air pressure or force pump. The acid, now ready for the production of the acid salt, is weighed and added slowly, under continual agitation, to a weighed amount of the alkali or neutral salt and thoroughly mixed. As the reaction requires considerable time for completion, it is advisable to add a slight excess of acid and then give ample time for the reaction to go to completion and all the free acid to disappear. At least 24 to 48 hours should be allowed for this aging process to take place. After proper aging, the acid salt is dried at a temperature of approximately 85 deg. C., preferably in a rotary or shelf vacuum drier, until a product containing not over 1 per cent moisture is obtained. A higher moisture content is detrimental both to the grinding or milling process and in the baking chemicals in which it is to be used.

The grinding of the acid salt is not a difficult operation. Under unfavorable weather conditions, considerable caking takes place, especially in damp climates. The grinding is followed by the screening operation, in which the powdered and granular portions are classified.

After the acid salt is properly granulated or powdered, it may be standardized to any strength desired by the addition of a neutral or inert substance, such as corn starch, dicalcium phosphate or calcium sulphate. The calcium sulphate cannot be classed as an inert substance and the present tendency is to eliminate the so-called sulphate phosphate from the baking industry. The leading phosphate manufacturers are taking the initiative and advising their customers to use only the full strength or the higher test phosphate.

It is sometimes the custom of the baking powder manufacturer to have the starch incorporated in the phosphate, by having the phosphate and starch mixed in a wet state before the drying and milling process.

The following analysis is typical of a high strength and a good grade of phosphate for baking or leavening purposes:

	Per Cent
Free phosphoric acid (H_3PO_4)	None
Monocalcium phosphate $CaH_4(PO_4)_2$	88.50
Dicalcium phosphate $CaHPO_4 \cdot 2H_2O$	8.00
Calcium sulphate ($CaSO_4$)	1.00
Iron and aluminum phosphates	1.00
Moisture and insoluble	1.50

Arsenic and lead, both under government allowance.

The dicalcium phosphate often may be found as high as 12 to 14 or as low as 1 to 2 per cent, the iron and aluminum, the calcium sulphate and the moisture each as low as 0.5 per cent and as high as 4 to 5 per cent.

Production of Sodium Phosphates

In the production of sodium salts of phosphoric acid the crude acid, as obtained in the decomposition process, is treated with soda ash or caustic soda instead of with lime for the removal of the soluble impurities. The soluble iron and aluminum salts become insoluble and are removed by filtration. The monosodium liquid may be concentrated and used for the production of crystalline or powdered monosodium salt. This monosodium salt may be used for the production of the sodium acid pyrophosphate, which is practically non-hygroscopic and a desirable acid leavening chemical. Or the monosodium salt solution may be treated with caustic or sodium hydroxide to form the neutral disodium salt or the alkaline trisodium phosphate. In the production of the trisodium salt, the solution may be concentrated to from 28 to 38 deg. Bé. in large iron boiling tanks or boxes by means of iron steam pipes, and crystals of the salt are obtained upon cooling. The mother liquor is used repeatedly until it is too dark in color and must then be discarded or be used in the production of substances such as dark laundry soaps or boiler compounds, etc.

Bone as a Source of Phosphoric Acid

Phosphoric acid and phosphates are produced from bone by treatment with sulphuric acid. The bone used for this purpose may be either the burned or unburned bone of the large packing industry or the discard or spent bone black of the oil and sugar industries. If care is taken in the selection of the bone, a very good grade of phosphoric acid can be prepared, from which neither the iron and aluminum nor the fluorine needs to be removed as is the case in rock phosphate. The weaker acid obtained may be treated for arsenic and lead as described for rock phosphate, then concentrated and used as liquid acid for the production of [illegible] salts or sold as concentrated liquid phosphoric

Legal Notes

By Wellington Gustin

A Point on Steamship Shipments

The Distilleries Chemical Supply Co. filed a libel suit against the steamship *Devona* to recover for freight paid for a shipment of formaldehyde and acetic acid, which was put on board and then taken off, at the captain's direction, before the boat sailed. It appeared that the vessel was chartered by the C. H. Pattingill Corporation, and that the freight was paid to the Caravel Steamship Lines, Inc., agent for the latter corporation. It appeared that the boat's owner was willing that the Caravel Steamship Co. might book freight for the vessel.

The case was tried in the Federal District Court. The claimant urged that no action against the boat would lie to recover freight, even if the goods are received on board ship, unless the owner received the amount paid, with which proposition the court agreed. And the admitted receipt of goods on board does not necessarily make the ship liable for damages for failure to transport. (The Esrom C. C. A., 272 Fed., 266.)

The trial court said there was nothing to indicate that the claimant intended to give the Caravel Steamship Lines authority to bind the ship by the receipt of freight, and the equities are with the claimant, which is asked to return moneys which it never received and which it never authorized another to receive in its behalf. Judge Hough laid down the principle applicable in the *Saturnes* (250 Fed., 407), wherein he said: "This litigation exemplifies a common tendency to regard any floating property, used in the performance of contract, as in some sort of a pledge or surety for satisfactory performance; such security to be enforced by asserted maritime lien. No such principle is known to the admiralty."

Therefore, the court dismissed the action of libel against the steamship but gave a decree against the Caravel Steamship Lines.

Lincoln Chemical Company Fails in Tax Case on Its Process

The case of the Lincoln Chemical Co. vs. Edwards, as Collector, reported in 272 Federal, 142, was to recover a refund of a part of the excess profits tax for 1917. The case depended on the meaning of the phrase "invested capital" and "nominal capital" as used in section 209 and as defined in section 207 of the revenue law of 1917. The company filed its return for 1917 and calculated its capital upon the basis of section 209—that is, it assumed it had "no invested capital," or not more than a "nominal capital." The treasury officials re-assessed the tax at a larger figure upon a basis that plaintiff had incorrectly applied section 209.

The chemical company was organized under the laws of New York with a capital stock of $10,000 by two persons, Riddle and Loeb. Riddle was an inventor and came to Loeb with a process for extracting cocoa butter out of cocoa shells, a byproduct. This process proved worthless, and Riddle continued his experiments to convert the process into one from which he could extract from cocoa shells a chemical substance, known as theobromine, allied to caffeine. Loeb incorporated the company to carry out the venture. Nearly $20,000 was spent in Riddle's further experiments upon the process in 1910, when it was completed. A contract was made with a manufacturing chemist to exploit the process on a royalty basis, but the sales of theobromine were so few that the royalty was never earned. All the company's assets were used up by 1914.

The company never manufactured any theobromine after 1910. The Great War in 1914 increased the demand for the product and the business which it conducted through the manufacturing chemist as manufacturer of the product became very profitable. During 1917 the assets of the company, therefore, consisted only of its cash on hand, the contract with the chemist for the manufacture of the product which was resold and the secret process finally perfected by Riddle. Its stock was $10,000 and its surplus, as stated, $13,000, of which over $7,000 was in cash. Its other assets were valued at $16,000.

Plaintiff's Claim Not Upheld by Court

The plaintiff asserted that there was only $200 of cash paid in, no tangibles remaining after 1913, no surplus "used and employed" in the business, and that the secret process was an "intangible" which must be taken at its "actual cash value" in April, 1909, which was shown to be nothing. The defendant argued that the sums spent upon the process, which did in fact increase its value by $19,000, should be taken as a surplus "used and employed" in the business.

The federal court in passing on this case held that the increased value of a process resulting from expenditures thereon figures as asset in estimating "earned surplus." It said where the only asset of a corporation was a secret process, which was intangible and of no value in April, 1909, the date on which the actual value of intangible assets was to be determined under the revenue law, but thereafter money was expended in developing the process, so that in 1917 the company had a surplus above its capital stock which was its only liability, the increased value of the process, due to the expenditures thereon, is to be considered as "earned surplus" which under the revenue law of 1917, section 207, is an element of invested capital, in determining whether the corporation had more than a nominal invested capital under section 209, though the increased value of the process due to the war could not be so considered.

The court found that the chemical company failed to prove that its value in 1917 over $10,000 was "not more than nominal." Hence for failure of proof judgment was rendered against it.

Germany's Potash Production, January-June, 1921

The German Potash Syndicate's semi-annual statement shows that the German potash production during the first 6 months of 1921 came to 4,454,261 metric tons of salts, or 497,373 metric tons of K_2O. This is equivalent to 548,105 short tons of actual potash. Sales during the same period amounted to 1,546,353 metric tons of salts, or 366,633 metric tons (404,030 short tons) K_2O, of which 1,408,911 metric tons of salts, or 333,281 metric tons (367,276 short tons) were for domestic use.

The Beet-Sugar Industry in the U. S. in 1920*

By C. O. Townsend

Pathologist in Charge, Office of Sugar-Plant Investigations

In the United States in 1919, 98 beet-sugar mills were standing and equipped for extracting and refining sugar from beet roots. The oldest one of the mills now standing was built in 1870 at Alvarado, Cal. During the summer of 1919, 4 of the 98 mills had been erected and equipped for the campaign of 1919-20, 6

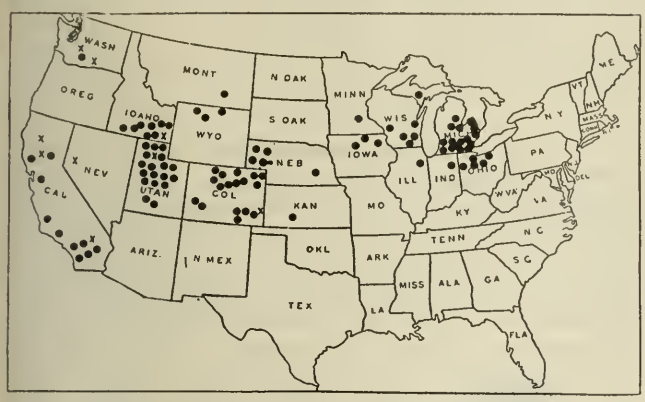

FIG. 1. LOCATION OF BEET-SUGAR MILLS

Dots indicate that the mill was in operation during the 1920-21 campaign. Mills that were standing idle are indicated by crosses.

additional ones were built and equipped for the handling of the 1920-21 crop, and 2 others are in process of construction, making a total of 106 beet-sugar mills now standing.

During the past 50 years 5 other mills have been built, but 3 of them have burned, 1 has been dismantled and 1 has been utilized for some purpose other than that of making beet sugar. Of the 106 beet-sugar mills now standing (Fig. 1), 26 were erected at some point other than the place where they are now located, but owing to certain limiting factors in beet-sugar production these 26 mills were removed to other locations; 2 of these were built in Canada and removed to the United States and 1 was built in this country and removed to Canada.

The 106 mills now standing are for the most part favorably situated for extracting and refining beet sugar under present conditions. In many instances certain limiting factors will need careful consideration and readjustment before a sufficient quantity of raw material can be assured annually to make all of them permanently successful. In many areas beet-sugar mills have been crowded in too rapidly, so that it has not been possible to readjust the farming operations and install the required drainage, irrigation and other improvements with sufficient rapidity to provide the necessary well-prepared acreage to supply enough sugar beets to insure a normal mill run. Consequently neither the mill owners nor the growers have received under these conditions a maximum return for the money and labor invested.

The production of sugar from beets in the United States for the 5-year period from 1916 to 1920, inclusive, is shown in the accompanying table.

*Abstract of Bulletin 995, Department of Agriculture.

Combined Crucible Holder and Thermocouple

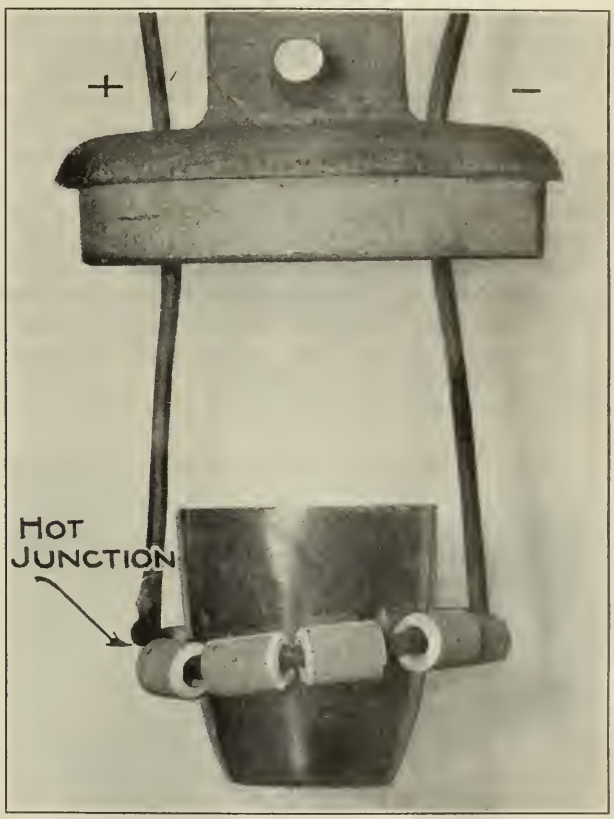
By Charles Y. Clayton

Professor of Metallurgy and Ore Dressing, Missouri School of Mines and Metallurgy

In "Standard Methods for Laboratory Sampling and Analysis of Coal," as published by the American Society for Testing Materials, the method for determining volatile matter is given as follows:

"Weigh 1 g. of the coal in a weighed 10 to 20 c.c. platinum crucible, close with a capsule cover, and place on platinum or nichrome-wire supports in the furnace chamber, which must be at a temperature of 950 deg. C. (±20 deg. C.)."

The design of furnace as given on page 10 of the



CRUCIBLE HOLDER AND THERMOCOUPLE

pamphlet shows an especially constructed furnace with thermocouple inserted through the bottom.

Wishing to utilize an ordinary crucible type furnace (nichrome resistor) the idea was conceived that if the crucible support was made of two dissimilar metals, the temperature of the furnace could be determined

without the use of a special furnace, with thermocouple entering through the bottom. The photograph shows the crucible support and thermocouple as designed by the writer for the use of the students in the Missouri School of Mines and Metallurgy. By drilling two holes in any furnace cover and inserting the two dissimilar wires any electrically heated crucible type furnace can be used for this determination.

By using a slightly different design of thermocouple and support, a very similar arrangement can be used for the heat-treating of small steel samples in the laboratory. Using this in conjunction with a recording potentiometer, a heating curve can be obtained showing the transformation point, and no calibration of the thermocouple is necessary.

Rolla, Mo.

X-Ray Diffraction Apparatus for Crystal Analysis

Apparatus for X-ray studies of crystal structure according to the method outlined by Edgar C. Bain in this journal Oct. 5, 1921, p. 657, has been developed by the research laboratory of the General Electric Co.

The apparatus (see accompanying figure) consists of a cylindrical case containing the transformer and X-ray tube, a number of film holders, or cassettes, and a control panel. The case is made of sheet iron, with doors in front to permit access to the transformer and tube. To avoid the possibility of accidents from contacts with live parts when the case doors are open, the supply circuit of the transformer is brought across the doors, so that it must be disconnected before the doors are opened. The top of the case forms a table, with a steel tower in the center. The X-ray tube is inside the tower, which is provided with slits to direct the rays through the substance to be analyzed. A second set of openings is provided for calibration purposes.

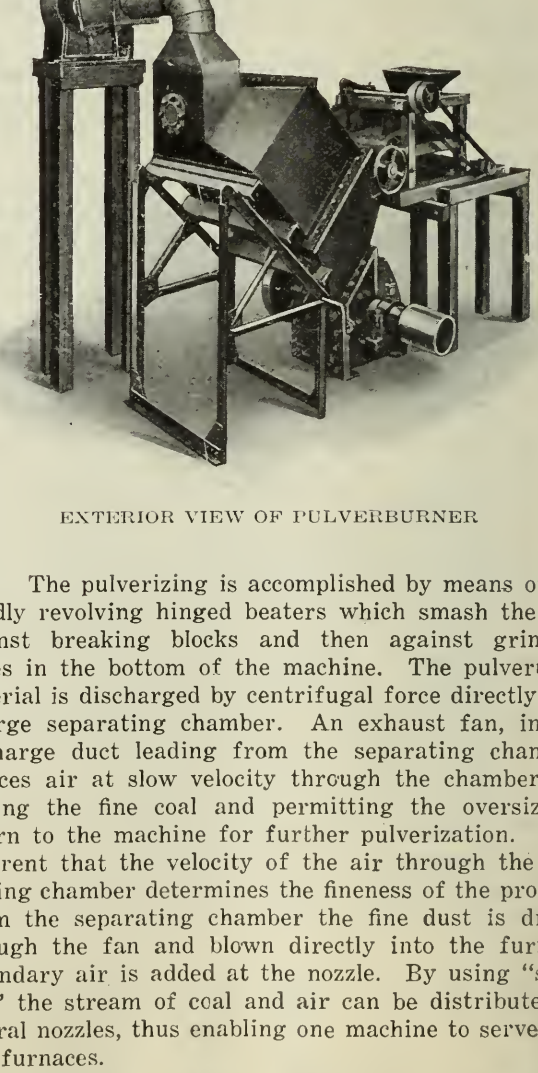
The substance to be analyzed, in powdered form, is inclosed in a small tube of special glass held in the cassette in a horizontal plane by spring clips. The cassettes, or film holders, slide on guides on the table fitting against the tower so that their glass tubes holding the specimens are in the path of the X-ray beam through the slit system. Rays passing through the substance are diffracted and register characteristic lines on the film which fits into the back of the holder.

X-RAY DIFFRACTION APPARATUS

The X-ray tube gives off molybdenum characteristic rays, of such long wave length that ⅛-in. iron or brass provides enough protection, and no lead is necessary. The tube is water-cooled; to prevent its running too hot, in case something happens to the water supply, a pressure-stat on the control board trips the breaker whenever the water pressure drops below normal.

The Pulverburner

The Pulverburner is a new machine for the preparation of powdered coal which has recently been placed on the market by the K-B Pulverizer Co., Inc., New York. The essential features of the machine are the pulverizing mechanism and the air-separating chamber. It will be seen from the accompanying illustration that the machine is fed by an automatic feeder of the bel



EXTERIOR VIEW OF PULVERBURNER

type. The pulverizing is accomplished by means of si rapidly revolving hinged beaters which smash the coa against breaking blocks and then against grindin plates in the bottom of the machine. The pulverulen material is discharged by centrifugal force directly int a large separating chamber. An exhaust fan, in th discharge duct leading from the separating chambe induces air at slow velocity through the chamber, re moving the fine coal and permitting the oversize t return to the machine for further pulverization. It i apparent that the velocity of the air through the sep arating chamber determines the fineness of the produc From the separating chamber the fine dust is draw through the fan and blown directly into the furnac Secondary air is added at the nozzle. By using "spli ters" the stream of coal and air can be distributed t several nozzles, thus enabling one machine to serve se eral furnaces.

By combining impact pulverization with air separ tion many advantageous features are obtained. Th

fines are removed from the machine as rapidly as produced so that the beaters are always operating on coarse material. This is an important item of power saving, even though impact pulverizing is known for its low power requirements. Coal that has not been dried can be successfully handled in this type of mill, and because of the air separator there are no screens to clog.

For efficient powdered coal burning close regulation is necessary, and this has been provided for in the Pulverburner. The rate at which the coal is fed is controlled by the automatic feeder by means of a cam arrangement that varies the speed of the belt. (The coal should be fed in such a size that a uniform "ribbon" is formed on the belt. Coal of 1 in. and under is satisfactory.) A magnetic pulley can be used with the feeder to prevent tramp iron from entering the machine. Quantity of air is controlled either by the speed of the fan, if a variable speed motor be used, or by a damper in the discharge passage. Air is introduced around the shaft. Velocity of the air through the separating chamber is regulated by two vanes in the chamber controlled through a worm and wheel. The beaters can be extended radially outward as they wear. The entire controlling mechanism can be operated by an automatic regulator.

The apparatus is designed to be driven by one, two or three motors. If one motor is used, both fan and feeder are driven from the pulverizer shaft. It is sometimes desirable to drive the fan from a separate motor, likewise the feeder.

The advantages claimed for the machine are its compactness, close regulation of fineness and air, simplicity, economy and adaptability to small as well as to large installations. It is being built in capacities up to 3 tons per hour.

Book Reviews

THE DESTRUCTION OF THE FRENCH METALLURGICAL PLANTS BY THE GERMANS (NOS USINES MÉTALLURGIQUES DÉVASTÉES) 1914-1918. Monograph edited by a group of engineers, with an introduction by Prof. *Léon Guillet*. Published, 1921, by *Revue de Métallurgie*. xxxiii + 270 pp. in quarto, with 300 illustrations. Price, 26 f.

In the introduction to the monograph *Nos Mines Métallurgiques Devastées* Prof. Guillet discusses the industrial importance of the French invaded region when compared with the similarly important regions of England (Lancashire, Chester, Derby, Leister, Nottingham, Stafford and part of York) and of the United States (Pennsylvania, Ohio, West Virginia and the states bordering the Atlantic from New Jersey to Florida) and gives a series of tables and maps showing the pre-war and war-time production of the French metallurgical plants.

The plan followed in the monograph is to give brief outlines of the history and pre-war importance of the plants and illustrative descriptions of their destruction. The plants described are:

Steel plants of the Denain & Anzin Co., by *Robert Jordan* (pp. 1-30); zinc plants of Noyelles-Godault, by *E. Demenge* (pp. 31-40); Denain plants of the Soc. Française de Constructions Mécaniques, by *L. Decroix* (pp. 41-48); aluminum plants of Mennesis (pp. 49-52); Homécourt plant, by *Paul Thomas* (pp. 53-63); Douai plant of the Etablissements Arbel, by *Alfred Brochard* (pp. 64-77); Joeuf plants of the Etablissements De Wendel & Cie., by *Jean Durand* (pp. 78-88). Ferrière-La-Grande plants of the Etablissements Delattre & Frouard, by *M. Lhonneur* (pp. 89-98); plants of Biache-Saint-Vaast (pp. 99-112); plants of the Micheville Steel Co., by *Paul Nicou* (pp. 113-130); plants of Mont-St.-Martin of the Longwy Steel Co., by *F. Meyer* (pp. 131-150); Rehon plant of Soc. de la Providence, by *P. German* (pp. 151-160); Aulnoye plants of the Soc. Métallurgique de Montbard-Aulnoye, by *P. Jarry* (pp. 161-166); Senelle plant of the Senelle-Maubeuge Metallurgical Co., by *Henri Lallement* (pp. 167-180); plants of Vireux-Molhain, by *M. Linard* (pp. 181-188); plants of the Forges et Aciéries du Nord et de L'Est, by *F. Villain* (pp. 189-204); plants of Givet of the Cie. Française des Métaux, by *A. Mercier des Rochettes* (pp. 205-220), and the plants of the Franco-Belgian Metallurgical Co. of Mortagne, by *M. Maréchal* (pp. 221-226).

Loose-leaf indexes of the illustrations in English, Spanish and Italian accompany the text.

A similar book has been published by the Société d'Encouragement pour l'Industrie Nationale, which is a reprint of an article by *L. Baclé* in the November-December, 1920, issue of the society's bulletin. In this book of 101 pages and 100 photographic views are described, in addition to some of the plants enumerated above, also those of Louvroil (Sté. Ame. de l'Espérance), Wringles (Sté. Métallurgique de Pont à Vendrin), Gorcy (Soc. Métallurgique de Gorcy) and Auboué (Soc. de Pont-à-Mousson). J. S. NEGRU.

THE CHEMICAL ANALYSIS OF STEEL-WORKS MATERIALS. *By Fred Ibbotson*, B.Sc., F.R.C., Sc.I., F.I.C. Pp. viii + 296. New York: Longmans, Green & Co., 1920. Price, $7.50.

This volume is a revision of "The Analysis of Steel-Works Materials," that was published under the joint authorship of Harry Brearley and Fred Ibbotson in 1902. The revision covers that part of the last-named book that treated of the analysis of the raw materials and the finished steel.

The book is divided into eight parts, including (1) General Processes and Notes. (2) Pig Iron and Steel. (3) The Analysis of Steel-Making Alloys. (4) Ores. (5) Refractories. (6) Slags. (7) Analysis of Fuels. (8) Boiler Water and Boiler Scale.

The book is well written and the methods are described in full detail. A most complete account of the reactions involved is to be found throughout the entire work. This is a valuable feature for students. However, some statements concerning methods need qualifications. For instance, the statement found on page 127 that "the determination of cobalt by the cyanometric method is of little or no value" is contrary to the facts. For it has been demonstrated that by the use of tartaric to keep the iron from precipitating in ammoniacal solution, and by always having at least 1 g. of iron present per 0.1 g. of Co, then cobalt can be determined in steel with the most satisfying accuracy up to 10 per cent. Cobalt steels never contain over 6 per cent and seldom over 5 per cent Co. This cyanometric method has been in continuous use in the United States for at least 13 years in some laboratories, and is to be preferred for speed, simplicity and reliability.

Certain methods and apparatus could well be omitted as obsolete, such as the determination of carbon by direct wet combustion and Geissler bulbs for weighing CO_2. The unwary beginner might try these and be severely discouraged with the art. But no doubt this is part of the author's scheme of giving some of the history of human progress in iron and steel analysis in its different phases.

A needless time-consuming detail, which is, also, still to be found in books by one or two other authors on iron analysis, is the recommendation given on page 142: Molybdenum is precipitated away from iron by saturating the solution with hydrogen sulphide. The "gassed" solution is then transferred to a pressure bottle; the latter is tightly stoppered and kept in boiling water for an hour. Yet on page 144 the author says that this boiling digestion under pressure is usually unnecessary in steel. Why give it at all then? For the fact is that it is always unnecessary. It would be better to emphasize the all-important detail in precipitating Mo by hydrogen to have the solution contain as little free acid as possible before passing any of the precipitant through it.

The author on page 57 outlines twelve different ways of

estimating phosphorus, and on the next page gives a thirteenth method which is described in detail. "An experienced operator can make thirty tests in a 7-hour day." The method is by "weighing as lead molybdate."

In the list of methods for manganese no space is given to the ancient and still honorable oxidation to permanganic acid by lead peroxide, which, when properly carried out, has the widest range accuracy of any of the methods up to at least 16 per cent of Mn.

On page 121 the use of a condensing lens is still advised to aid in the cynanometric titration of nickel in alkaline citrate solution, whereas this was made entirely avoidable 14 years ago (see *J. Am. Chem. Soc.*, vol. 29, No. 8, August, 1907) by the simple expedient of adding 12 g. of citric acid instead of 3 g. per gram of steel. The magic lantern detail should be omitted, as it was but little help at best.

In describing the determination of carbon by combustion one would expect to find an illustration showing an electrically heated combustion furnace with a modern purification and absorption train, but a gas furnace only is shown with a verbal account of the accompanying train. Mention is made that electric furnaces are used.

This work contains much excellent information and no iron and steel analyst can afford to have it absent from his ready reference shelf, even though it already be a 5-ft. one or a 10-ft. one. C. M. JOHNSON.

* * *

AN INTRODUCTION TO THE PSYCHOLOGICAL PROBLEMS OF INDUSTRY. By *Frank Watts.* 240 pp. New York: The Macmillan Co., 1921. Price $5.

This book by the lecturer in psychology in the University of Manchester and in the department of industrial administration, Manchester College of Technology, is the most interesting contribution to the literature of this subject that has recently appeared.

Perhaps the thing that Englishmen do best, as compared with American writers, is the discussing of a subject in a thorough and well-rounded manner, and yet in an interesting way. American writers are fluent in the production of literature on the details of a subject, but when it comes to a well-rounded summary on a whole topic, very often the best treatise is found to be by an Englishman. It is certainly true in this case, and is correspondingly curious, inasmuch as although study of the psychological problems of industry began first in this country and has been carried on by an immensely greater number of people here the best book on the subject now comes to us from England.

The reviewer is inclined to suspect that the author has probably a much more thorough acquaintance with industry than the American psychologists who write on this topic, and of course a good deal of the American literature has come from the pens of persons who are familiar with industry but who have a rather imperfect knowledge of psychology. At any rate, anyone who is interested in getting a reasonable grasp of the new viewpoint of the importance of mental problems in industrial life cannot do better than to read this book.

Evidently the author has been in fairly close touch with the work of the Industrial Fatigue Research Board, for his book begins with a discussion of industrial fatigue and inefficiency, and the first section of Chapter II deals with muscular fatigue. The second section is on organic variability, and the third section on mental fatigue. This section indicates the thoroughness of the study and how well balanced the author is, for fatigue investigators generally have continued to overlook the importance of mental fatigue in the study of the problem, although even the laboratory investigators know that if the subjects have worked an ergograph to the point of exhaustion and are then told that with the removal of a pound weight they can continue to work, but instead a pound weight is added, they will go on working just as happily as though the pound weight had actually been removed. There are those in this country who believe that mental aspects of industrial problems far outshadow the importance of those physiological aspects that have heretofore received practically all of the intensive study that has been given to the subject.

The third chapter deals with the elimination of fatigue from work by motion study, and is a good brief review of the work done on this topic. The chapter on vocational education is also good, and this is especially true of the third section, which deals with intelligence tests, and the criticisms which are made of the application of intelligence tests to industrial life are both temperate and apparently entirely sound. The chapter on scientific management and labor is perhaps the best in the book, and is an extremely interesting summary of the abundant literature on this subject. The chapter on industrial unrest similarly summarizes, in a brief and readable way, the rather abundant literature that to most operating men would seem so vague and far from their immediate problems as to be unattractive to them. When all these ideas are brought together, in their relation to one another, and concisely summarized, their importance and usefulness becomes apparent. The concluding chapter deals with the creative impulse in industry and deals with such apparently diffuse sub-topics as the decline of the traditional types of craftsmanship, modern recreation, ideals in industry, copartnership, state socialism, syndicalism, industrial democracy and industrial education. The author has brought these together, however, so that their bearing on one another becomes apparent. In other words, he has proceeded in his book from the central core of his subject out to the periphery. Each chapter is supplemented by a brief list of the more important works on the topic, which will be extremely valuable to those who care to pursue any of the topics further. Altogether, this is a most satisfactory book, and one that ought to be not merely in the library of anyone interested in industrial work, but kept at hand where it is easily available for re-reading from time to time. T. T. READ.

Recent Chemical & Metallurgical Patents

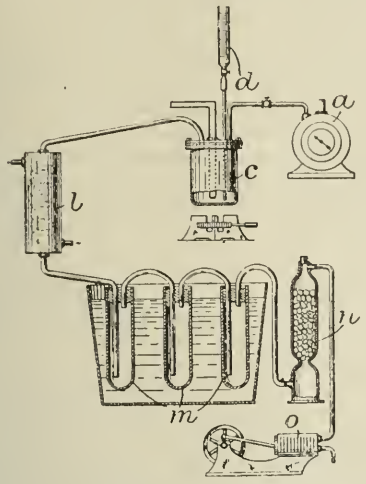
British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Colloidal Elements and Compounds.—Colloidal solutions of copper, silver, mercury, cerium, arsenic and antimony, or of their insoluble compounds, are prepared by treating these metals or their compounds for some time at temperatures above 100 deg. C. with waste sulphite cellulose liquor or waste soda cellulose liquor. The metal or its insoluble compound in the powder form may comprise the starting material; or a soluble salt of the metal may be added to the cellulose waste liquor and the metal or its insoluble compound formed therein during the process either by the addition of precipitants, such as alkali, or by the reducing action of the cellulose waste liquor itself, with or without other reducing agents, such as sulphuretted hydrogen. The colloidal product may be precipitated or purified in any known manner and utilized in medicine, veterinary surgery, tanning, the preparation of cosmetics, for the protection of plants and the impregnation of wood or fabric. The colloidal products may be employed per se, or in conjunction with oil, resin, and other organic emulsions, or with the addition of colloids or filling substances. In the case of plant protection, such materials as aluminum hydrate, aluminum sulphate, gypsum, barium carbonate, lime or copper-lime mixtures may be added to the colloidal products. According to the examples: (1) Colloidal mercury is prepared by heating mercuric chloride with purified waste sulphite cellulose liquor; preferably with addition of caustic soda or potash; or by heating mercuric oxide with the lignine substances extracted from waste sulphite cellulose liquor in the known way; (2) copper sulphate, on heating with waste sulphite cellulose liquor and soda lye, is converted first into colloidal copper protoxide and then into colloidal copper; a similar result is obtained by heating powdered copper oxide with a mixture of waste soda cel-

lulose liquor and waste sulphite cellulose liquor; (3) colloidal silver is obtained by the heat-treatment of silver oxide with waste sulphite cellulose liquor; (4) colloidal sulphide of arsenic results from the introduction of sulphuretted hydrogen into a hot solution of arsenious acid in cellulose waste liquor. (Br. Pat. 169,758. Chemische Fabriken Dr. K. Albert und L. Berend, Amöneburg, near Biebrich, Germany. Nov. 23, 1921.)

Concentrating Ores.—Reagents for use in concentrating ores by froth flotation are obtained by subjecting organic substances to a partially decomposing heat in the presence of air or oxygen. The organic substances treated may be liquids or solids—for example, kerosene, gas oil, bitumen, bituminous coal, wood or mineral-frothing agents such



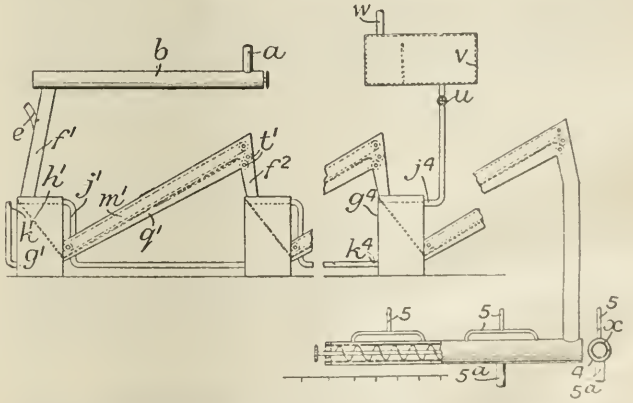
as oleic acid or cottonseed oil—and the oily or aqueous condensates or gaseous or vaporous distillates of the decomposition may be used in the flotation process. In the apparatus shown in the figure, for the treatment of liquids, the material to be treated is fed from a burette *d* to a heated chamber *c* to which a regulated supply of air is admitted from a meter *a*. The products are drawn by a pump *o* through condensers *l*, *m* and a scrubber *n*. In some cases the condensers may be omitted and the products passed direct to the flotation apparatus. Apparatus for treating solids may comprise a heated retort or chamber for a charge of material and a system of condensers, etc., similar to that shown in the figure. In another case, refractory material saturated with kerosene may be treated by igniting the kerosene, sucking air through it and passing the products to the flotation apparatus. (Br. Pat. 169,288. Minerals Separation, Ltd., London; E. W. Wilkinson, New York. Nov. 9, 1921.)

Resinous Compounds; Shellac Substitute.—A substitute for shellac consists of spirit copal, preferably Manila or Macassar copal, with 6 to 8 per cent of oleic acid, preferably in the form of Australian oleine; candelilla wax, resin and dyes are added to give imitations of different varieties of shellac. The materials are melted and stirred together for 2 hours in a steam-jacketed vessel, and then poured out and passed between rollers, which may be indented to form "buttons." The rollers may be cooled. (Br. Pat. 169,829. E. A. Muskett, Enfield, Middlesex. Nov. 23, 1921.)

Treatment of Aluminum Alloys.—To prevent surface corrosion, aluminum alloys in which aluminum predominates, and particularly those containing copper, manganese, and magnesium, are first boiled in an alkaline solution, such as of caustic soda, then treated in a steam bath, then immersed in a solution of zinc phosphate containing iron phosphate in suspension and of gradually increasing temperature, and finally washed in hot water. The first step may be effected in a water-jacketed porcelain vessel heated to 160 to 180 deg. F., the article being boiled in a caustic soda solution of ½ per cent strength for about 20 minutes until a black oxide is formed. Preferably the vessel is heated in a gas oven with a ventilating flue so that the article can be quickly dried on withdrawal from the solution with the aid if necessary of a warm jet of compressed air. The article is then suspended in a steam bath for a few minutes only until the coating becomes greenish yellow. Ammonia in small regulated quantity is introduced to prevent acidity during the steaming. A paste formed by the treatment of granular zinc with specified proportions of orthophosphoric acid and boiling water is dissolved in water, 1 oz. to 1 gal., and the solution is boiled in an iron tank for a few hours daily with small additions of the paste, pieces of scrap iron or steel being suspended in the solution. Equal parts of the residual liquor and cold water, with a small quantity of a saturated solution of the paste, form the phosphate solution into which the article is immersed direct from the steaming for 10 to 15 minutes. The coating changes in color to gray and finally pink, if the solution becomes stronger, and when all the yellow has disappeared the article is washed. (Br. Pat. W. B. Brunskill, Cark-in-Cartmel, Lancashire. Nov. 23, 1921.)

Dyeing Cellulose Acetates.—For the purpose of rendering them amenable to dyeing, threads or fabrics containing cellulose acetates having 2-2½ acetyl groups per cellulose molecule are treated, at temperatures between 40 and 80 deg. C., with an alkaline saponifying agent, the quantity of which is restricted to that necessary to produce a diminution in weight of not more than 10 per cent in the cellulose acetate originally present. The saponification treatment may precede the dyeing operation, or they may be performed together in the same bath. As saponifying agent, caustic soda, caustic potash or carbonate of soda may be employed, in concentration not greater than 1 per cent; any dyes, such as substantive, acid, basic, vat or sulphur dyes, are applicable, either directly or with the use of mordants. The provisional specification includes the treatment of any cellulose acetate lower than the triacetate and states that the restricted saponification may also be effected by using excess saponifying agent and limiting the time of action thereof. (Br. Pat. 169,741. British Cellulose & Chemical Manufacturing Co., Ltd., London, and J. F. Briggs, Spondon, near Derby. Nov. 23, 1921.)

Extracting Fats.—In a counter-current process for the extraction of oils, etc., from crushed seed or other vegetable matter by means of volatile solvent and in which solvent is expressed from the mass after each immersion, the meal from a pipe *a* is conveyed through a jacketed conduit *b* and falls on to a preferably inclined screen h^1 in a tank g^1 so that its progress is retarded while it mixes with used solvent from a pipe j^1. The meal is then conveyed to wringing rollers t^1 through a conduit m^1 having its bottom perforated from above the level of the pipe j^1 so that drained



or expressed solvent runs down an outer conduit q^1 to the tank g^1 but below the screen h^1. The pressed meal falls down a conduit f^2 and is passed through a series of similar tanks, conduits and rollers to a perforated conduit *x* in which it is freed from solvent by steam or vapor from a pipe 5a in the lower half of a divided jacket 4, the vapors being drawn off to a condenser through pipes 5. Pure solvent is fed from the tank *v* to the last tank g^4 by a valve *u* and pipe j^4 and through the series by pipes k^4 and j^1 to the last outlet pipe k^1, which leads to a solvent-recovery apparatus. The recovered solvent is returned to the tank *v* by a pipe *w*. Solvent vapor in the tank g^1 or pipe f^1 is drawn D. the recovery apparatus through pipe *e*. (Br
M. Whitehead and E. Scott, both in
Nov. 23, 1921.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Well-Known Glass Manufacturer Probable Ambassador to Germany

The nomination of Representative A. B. Houghton, of New York, to be Ambassador to Germany probably will be sent to the Senate this week by President Harding.

Mr. Houghton has been associated with the Corning Glass Works snice 1889, serving as second vice-president from 1903 to 1910, as president from 1910 to 1918 and is now chairman of the board of directors. He is also vice-president of the Ephriam Creek Coal & Coke Co. and a director of the Metropolitan Life Insurance Co.

Program for February Meeting of Institute of Metals Division

Following is the preliminary announcement of the forthcoming session of the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers, held in connection with the February meeting in New York:

Monday, Feb. 20, 2 p. m. Chairman, W. H. Bassett.

E. E. Thum, "Results Achieved by the Corrosion Committee of the British Institute of Metals."

R. J. McKay, "Corrosion by Electrolytic Concentration Cells."

L. McCulloch, "Experiments With Sherardizing."

W. H. Bassett and C. W. Davis, "Spectrum Analysis in an Industrial Laboratory."

H. J. Roast, "Arsenic-Bearing Metals."

Tuesday, Feb. 21, 10:45 a.m.

First annual lecture of the Institute of Metals Division, Prof. Wilder D. Bancroft, "Colloid Chemistry and Metallurgy."

Tuesday, Feb. 21, 2 p.m., Chairman, W. H. Bassett.

Z. Jeffries and R. S. Archer, "The Slip Interference Theory of the Hardening of Metals."

E. C. Bain, "Crystal Structure of Solid Sólution by X-Rays."

P. Hidnert, "Thermal Expansion of Copper and Some of Its Important Alloys," (Bureau of Standards.)

P. Hidnert and W. Souder, "Thermal Expansion of Nickel, Monel Metal, Stellite, Stainless Steel and Aluminum," (Bureau of Standards.)

W. McG. Peirce, "Studies on the Constitution of Binary Zinc Base Alloys."

There will also be a dinner and meeting of the executive committee and past officers of the division at the Engineers Club at 5:30 on Monday, Feb. 20.

All of the metallurgical members of the Institute will be interested in Prof. Bancroft's lecture, and the innovation is planned as the first of a series which will aid the busy members to get acquainted with the most recent advances in their science.

Senators Sidestep Dye Investigation

Senator Borah of Idaho has found that it will be impossible for him to devote the time likely to be required as a member of the sub-committee which will conduct the dye investigation recently ordered by the Senate. Nearly every member of the Judiciary Committee has been urged to accept service on this sub-committee, but all have declined, since they foresee that this investigation will be of long duration and will require a great deal of their time. While there is still hope that some member of the committee can be induced to accept this service, it is probable that some delay will result before the sub-committee can be completed. Senator Shortridge of California has accepted the appointment as chairman of the sub-committee and Senator Reed has consented to represent the minority on the committee.

Study of Plant Depreciation Planned by U. S. Chamber of Commerce

Practical studies by the various industries to ascertain a normal rate of depreciation shown by experience on buildings, machinery, etc., which may be used as a basis for reckoning depreciation in individual plants is urged by the Fabricated Production Department of the Chamber of Commerce of the United States. Such studies have the approval of the United States Treasury Department.

It is not the purpose to create within any industry inflexible standard rates of depreciation, but it is proposed to set up something that may be used as a guide to fit usual conditions, as explained in a bulletin in which the Fabricated Production Department puts forward its recommendation.

"Trade associations representing a single line of industry," says the bulletin, "are particularly well fitted to take up such studies. In lines not so organized groups may be formed to perform the same function."

The Fabricated Production Department of the National Chamber has been working on this problem for some time. The announcement that the Treasury Department approves investigation and study along the lines suggested will be of unusual interest to business men, particularly manufacturers.

Additional information may be obtained from the Fabricated Production Department of the Chamber of Commerce of the United States.

New Muscle Shoals Proposal Submitted by Shipbuilder

A new proposal for leasing and operating the Muscle Shoals plants has been received by Secretary Weeks from Frederick E. Engstrum, president of the Newport Shipbuilding Co.

Mr. Engstrum proposes to form a corporation which will guarantee (under bond) to complete the power stations, dams Nos. 2 and 3 and such other works as may be agreed upon, and to lease the property for a period of 50 years. Construction will be started within 60 days from date of possession and completed within 4 years.

Excess power would be sold by the company at a minimum price of 1 mill per kw.-hr. It is proposed to operate the nitrate plants by diverting to this purpose the net receipts, up to and including 1 mill per kw.-hr., from the sale of the excess power, over and above that required to operate the property, in addition to the gross receipts from the sale of the nitrate products (at prices and terms to be fixed by the government). At least one of the nitrate plants would be put in operation within 1 year from date of possession. A research department would also be maintained in cooperation with the government for the purpose of developing the processes for nitrogen fixation.

In consideration of the performance of these proposals the government would agree to pay to the power company $36,000,000, in four equal annual installments. All of the proceeds from the sale of power in excess of 1 mill per kw.-hr. would be retained by the power company as its compensation for the undertaking of this proposal.

Miniature Experimental Tannery Built at Columbia University

What is said to be the smallest complete tannery in the world has recently been completed at Columbia University, New York, under the direction of Prof. A. W. Thomas. The tannery is about 2½ ft. long and was designed to handle raw hides under a scientific tanning process. The purpose of the plant is to provide means for a careful and scientific study of the chemical action of tanning.

Biscuit and Cracker Manufacturers' Association Appoints New Director

As a step in the development of the Technical Bureau of the Biscuit and Cracker Manufacturers' Association, the technical committee has been authorized to obtain the services of A. V. H. Mory, well known for his success in the organization and direction of industrial laboratories. Mr. Mory's experience has been broad rather than special, but has been largely in food lines. Entering the employ of Armour & Co. as a chemist, he became head of the chemical department of that company's Kansas City plant. He later entered the Bureau of Chemistry at Washington and was appointed chief of the government's food and drug inspection laboratory at Kansas City, Mo. While in government service he was invited by Sears, Roebuck & Co. to develop an organization for the technical control of their whole line of merchandise and served there for 9 years as director of their technical laboratories. Two years ago he was invited by Procter & Gamble to reorganize and become executive head of the greatly enlarged chemical division then planned by them, but a short time ago he returned to Chicago to engage in consulting practice, specializing in organization work of the sort he is undertaking for the Biscuit and Cracker Manufacturers' Association.

Mr. Mory was chairman of the Chicago Section of the American Chemical Society in 1916 and later one of the Society's councilors at large. For a number of years he has been on the editorial advisory board of the *Journal of Industrial and Engineering Chemistry*. He is a member of the Chemists' clubs of New York and Chicago and enjoys wide acquaintance in food control circles.

Improved Business Conditions Indicated by Increased Operations of Plants

Paper. The Northern Paper Mill, Green Bay, Wis., is operating its plant at full capacity and has added about fifty operatives to the normal working force. All six machines at the mill are on a day and night schedule.

Glass. The Owens Bottle Co., South Glassboro, N. J., has established operations with full working shifts and purposes to continue production throughout the winter season.

A number of idle glass plants in the vicinity of Millville, Vineland and Bridgeton, N. J., are preparing for the early resumption of operations.

The three window glass manufacturing plants at Kane, Pa., are arranging for a continuance of production throughout the winter season, these being the American Window Glass Co., Pennsylvania Window Glass Co. and the Kane Glass Co. The plants are giving employment to a total of about 1,000 operatives.

Ceramic. The Fords Porcelain Works, Perth Amboy, N. J., manufacturer of sanitary ware, is operating its three local plants at full capacity.

The Perth Amboy Tile Works, Perth Amboy, N. J., manufacturer of floor tile and fine ceramics, is operating at capacity and has construction under way on an addition, to be placed in service as soon as completed.

Rubber. The B. F. Goodrich Co., Akron, Ohio, has added about 1,000 men to the working force at its tire-manufacturing plant during the past 3 weeks. Production is now in excess of 16,000 tires a day. The aëronautical department at the rubber mills is working at full capacity on government orders.

The Phoenix Rubber Co., Akron, Ohio, is planning to resume production at its local plant at an early date.

The Firestone Tire & Rubber Co., Akron, Ohio, is increasing the working hours at its plant. Additional workers have been added to the force.

Oil. The Francis Refining Co., Ada, Okla., has commenced operations at its new local oil refinery, and will run under a full-time schedule.

The Sinclair Refining Co. is arranging for the immediate resumption of operations at its refinery at Coffeyville, Kan. Reconstruction of a number of departments is now under way, involving improvements costing in excess of $1,000,000.

Copper. A number of copper companies in the Butte, Mont., district are perfecting arrangements for a resumption of operations at their mines and reduction plants, effective Jan. 16. The companies include the Anaconda Copper Mining Co., the Butte & Superior Mining Co., the Davis Daly Copper Co., the Tuolumne Copper Co. and the North Butte Mining Co. A wage reduction, based on a graduated scale approximately 50c. a shift, will go into effect at the time noted.

Iron. The McKinney Steel Co., Cleveland, Ohio, is arranging for the immediate resumption of operations at its Colby-Ironton iron mines, Bessemer, Mich., giving employment to about 500 men. The properties have been idle since last May.

The Charcoal Iron Co., Detroit, Mich., is making improvements at its mines in the Manistique, Mich., district, and proposes to place the plant in operation by Jan. 16. Effective early in January, the company will operate its Yale iron mines at Bessemer, Mich., under a day and night shift.

Steel. The Wickwire-Spencer Steel Co., Buffalo, N. Y., has increased production at its finishing mills to normal, or 100 per cent capacity.

Resumption of operations at the sheet mills of the Inland Steel Co. at Hammond, Ind., brings the company's production to 50 per cent capacity.

Zinc. The New Jersey Zinc Co., Palmerton, Pa., is increasing operations at its local works and it is expected that all departments will be running full, with regular working forces, at an early date.

Personal

Dr. JEROME ALEXANDER is now president of the Uniform Adhesive Company, Brooklyn, N. Y.

Dr. CHARLES BASKERVILLE, head of the department of chemistry, College of the City of New York, is seriously ill with pneumonia.

A. E. BUCHANAN, JR., formerly a member of the chemical department of E. I. du Pont de Nemours & Co., has assumed the duties of assistant editor on the staff of CHEMICAL & METALLURGICAL ENGINEERING.

S. G. BYAM, chief chemist at the Fairfield rubber works of E. I. du Pont de Nemours & Co., has resigned from that position to become chief chemist at the Plymouth Rubber Co., Canton, Mass., with entire charge of the technical development.

H. E. HANDY, who has been the metallurgist on the staff of the Washington Steel & Ordnance Co., has removed from Washington, as a result of the permanent closing of the plant and liquidation of this company's affairs. His new address is 773 Elmwood Ave., Providence, R. I.

H. T. HERRICK is with the American Aniline Products, Inc., at Lock Haven, Pa., and not Lock Haven, Conn., as stated in our issue of Dec. 21.

Dr. ERNEST FOX NICHOLS has resigned the presidency of the Massachusetts Institute of Technology and his resignation has been accepted by the executive committee of the corporation. His decision resulted from the unfavorable condition of his health. Dr. Elihu Thomson, of Swampscott, chief consulting engineer of the General Electric Co., who served as acting president after the death of President Richard C. Maclaurin in January, 1920, has again been appointed to that position.

WILLIAM RUSSEL, London representative of the Dorr Co., has recently made a professional trip to the Rand district of South Africa and is now in the Congo.

Dr. C. G. SCHLUEDERBERG of the Westinghouse Electric & Manufacturing Co. sailed on Jan. 7 for a trip to South America. He will visit points in Peru, Agentina, Chile and Brazil.

The newly elected officers of the American Chemical Society for 1922, are as follows: President, EDGAR F. SMITH; directors, M. C. WHITAKER and W. R. WHITNEY; councilors-at-large, A. M. COMEY, E. C. FRANKLIN, W. D. HARKINS and W. LEE LEWIS.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Announcing a Weighted Index of Chemical Prices

In order to assist our readers in following the week-to-week fluctuations in the chemical market and also to provide a ready means of comparing the trend of these prices with those of other commodities, CHEMICAL & METALLURGICAL ENGINEERING has undertaken the compilation of a weekly index number for chemical prices. It is apparent that the simple average of the prices for a selected group of chemicals would be of little value, since it fails to take account of either the relative importance of the article or the proportionate increase or decrease in its price. In order to avoid these difficulties CHEM. & MET. has adopted a system of weighting based on production and imports.

The base of 100 to which these prices were compared was calculated on the average monthly wholesale prices for the year July 1, 1913, to June 30, 1914. These figures are identical with those prepared and used by the Chemicals Section of the War Industries Board in connection with its comprehensive studies of prices during the war.

How It Was Obtained

It is believed that a detailed explanation of how the weighted index number was obtained will be of some interest and at the same time will give a clearer idea of what the number means and how it may be used. In the first place, twenty-five commodities were selected on the basis of their importance as representing qualitatively and quantitatively the principal component branches of the chemical industry. These chemicals included in the index number are as follows: Acetic acid, citric acid, hydrochloric acid, nitric acid, sulphuric acid, ethyl alcohol, methyl alcohol, anhydrous ammonia, ammonium sulphate, barium chloride, bleaching powder, borax, caustic potash, caustic soda, copper sulphate, formaldehyde, glycerine, crude potassium carbonate, salt-cake, soda ash, crude sulphur, benzene, aniline oil, cotton-seed oil and linseed oil.

The second step in the process was obtaining the statistics for the production and imports of each of these commodities for 1919. That year was selected primarily because of the completeness of the statistics compiled by the Census of Manufactures. A few of the articles included in the index are exported in considerable quantities, but these amounts were not taken into consideration, because it was intended that the index should represent total activity in the wholesale chemical market rather than merely the selling for consumption in this country.

The next step in the process consisted in multiplying the monthly prices by the commodity weights—i.e., the sum of the production and the imports. The sum of the figures thus obtained made up the total value of the year's business in these twenty-five chemicals, and from these data it was a comparatively simple matter to calculate a factor representing the relative importance of the separate commodities.

Finally, these war figures were compared with and expressed in terms of the pre-war base, which, as previously stated, was the average for the year ended June 30, 1914.

What It Shows

Wholesale prices of chemicals were not published in this magazine prior to 1917 and no effort is made in the present article to trace the trend of prices during the period 1914-1916. The monthly index numbers for the 5 years which have elapsed since that time are presented in the accompanying table. They show that during this period the chemical market has followed an unusually interesting course. From 191 in March, 1917, the index number had a gradual and consistent rise to 285 early in 1918. This high level of prices was maintained during almost the entire year, although immediately after the armistice, the cessation of the war-time demands and the lapse of the price control exercised by the government resulted in a noticeable decline in prices. The index number fell from 279 in November, 1918, to 227 in April, 1919. Shortly thereafter occurred the post-war boom during which the prices again rose almost to the levels reached in 1918. Unfortunately, however, our prosperity was short-lived. Beginning in October, 1920, there occurred one of the most precipitious declines of prices which history has ever recorded. The CHEM. & MET. index number fell off 74 points in 2 months and 123 in 6 months. In April, 1921, the prices of these chemicals stood at the lowest level noted during the 5 years. The remainder of 1921 saw only minor fluctuations in the chemical market, although by August the index number had risen to 158. From October and through the remainder of the year there has been a further, although very slow, decline. The past week, however, has been characterized by slight increase in prices, the index number showing a gain of 1.19 points.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

	1917	1918	1919	1920	1921
January	198	281	262	242	181
February	195	285	250	252	166
March	191	281	233	252	157
April	207	286	231	261	140
May	222	267	227	279	143

Nation-Wide Reduction of Inventories Reported by Manufacturers

One of the outstanding features of the annual reports now being issued by manufacturers in every branch of industry is the emphasis placed on reduced stocks, both of raw materials and finished products. The national scope of this readjusting process has also been shown in an interesting manner by the Harvard University Committee on Economic Research. This committee points out that in July of this year the index for the volume of manufacturing reached its low point of 68.5 per cent of the average for 1919 and has since increased to about 90. The average for the first 10 months of 1921 was 79 per cent. On the other hand, car loadings for the first 44 weeks of this year are reported to be 94 per cent of the 1919 loadings during the corresponding period. Since car loadings serve as a direct index of goods distribution, it would appear that distribution has considerably exceeded production during 1921 and that therefore inventories must have been materially lessened.

Du Pont Dividend

A cash dividend of 5 per cent, or 25c., on both common and preferred stock has just been declared by the Du Pont Chemical Co. of Wilmington, Del. The dividend is payable Feb. 6 to stock of record Jan. 25.

Court Holds That Fusel Oil Is Not Subject to Import Control

The District of Columbia Court of Appeals on Jan. 3 upheld a decision of a lower court which had refused to restrain the Secretary of the Treasury from permitting large quantities of foreign fusel oil to enter the country in competition with butanol, which was alleged to be a similar product. Complaint had been brought by the Commercial Solvents Corporation of New York under the dye and chemical control section of the emergency tariff act.

The plaintiff contended that the Secretary of the Treasury had erred in declaring that fusel oil was not a synthetic organic chemical and therefore was not subject to the import control exercised over this class of chemical products. The judge refused to grant a temporary injunction to the butanol manufacturers and in doing so declared that he would not attempt to compare his technical knowledge with that of the Treasury Department experts. The question was clearly a matter of technical knowledge, the court held, and the judgment of the lower court was affirmed.

Is Calcium Carbide A Synthetic Organic Chemical?

The hearing of the claim of the British Cellulose & Chemical Manufacturing Co. to have calcium carbide included in the schedule of the safeguarding of industries act, which imposes a duty of 33⅓ per cent on the value of articles imported, was held in London on Dec. 22. The act requires all synthetic and organic substances to be in the schedule, and the point in dispute between the Cellulose company and the British importers of calcium carbide is as to whether this substance is organic or inorganic. It was stated in the course of a scientific argument that this question had never become acute until the present hearing.

Evidence in support of the case for the Cellulose company was continued. John Rogers, technical manager of Nobels Industries, Ltd., agreed with former witnesses that calcium carbide was synthetic and organic chemical. Matthew Dickie, general manager of the Cellulose company, said that at the request of the government his company erected a calcium carbide plant at a cost of £600,000. During 1919-20 the company was producing 19 tons of carbide per day. This was sold at that time at £26 per ton, although the cost of production was £33 per ton. Of course they could not carry on and the plant had been idle since 1920. They could have carried on if they could have obtained £40 per ton, but against that figure they had to compete with the price of £17 per ton charged by Austrian and German manufacturers. If the duty under the act was imposed it would enable his firm to resume operations. The inquiry was adjourned until Jan. 14, when the proceedings will be in private.

The Coal-Tar Products Market 1920, 1921 and 1922

The present condition of the coal-tar products market is due directly to the forces that have been at work during 1920 and 1921. In 1920 America reached its banner year of foreign business. Resale merchants contracted for large supplies of intermediates, with prospects of making turnovers at large profits to foreign customers. American products were greatly in demand and even though the exchange was very unfavorable, there were no other countries in a position to compete successfully with the United States. In the midst of this flurry of speculation and immense profits came the sudden reversal of affairs following the announcement of the collapse of the Japanese financial system. America with its inflated values became the center of deflation. Prices on all commodities took a sharp decline and speculators who had heavy stocks of chemical products added to the economic upheaval. Weak holders began to make their appearance and presently tremendous stocks were thrown into the market to realize ready cash.

By the end of 1920 the American export business in dyes was practically at a standstill. Large shipments of American-made products were brought back and dumped on the open market at ridiculously low prices. Consumers were losing their interest and would purchase only for immediate necessities. In the meantime, Germany became a more important factor in the domestic market. The extremely favorable position of the mark and the low production costs gave Germany an advantage over the rest of the world. At the beginning of 1921 the resale merchants were overstocked with dyes and intermediates and many of the plants of the domestic producers were closed tight waiting for favorable developments.

The coal-tar products market remained practically unchanged during 1921. An occasional advance on some particular commodity might be reported, but in general there were no outstanding features in the market. Prices have been reduced by producers consistent with manufacturing costs. However, it is believed that there will have to be a great many more revisions before the industry can compete in any successful manner with the German interests. The domestic producer maintains that freight rates must come down and that a protective tariff must be enacted.

COMPARATIVE PRICES OF COAL-TAR PRODUCTS, JANUARY, 1921–JANUARY, 1922

Article	Jan., 1921	April, 1921	June, 1921	Oct., 1921	Jan., 1922

Resorcinol, tech., lb.	2.75	1.75	1.75	1.50	1.50
Toluidine, mixed, lb.	.45	.40	.40	.43	.35

The past few weeks have provided a few encouraging features. Phenol has been advanced and so also have the quotations on benzene and naphthalene. Japan has again become a consistent buyer of heavy tonnages of phenol and exports of benzene to England have resulted in a noticeable shortage in the domestic market. The consuming industries have again shown an urgent demand for naphthalene and have purchased large quantities on contract for the rest of the year. With these outstanding features and the general feeling of confidence that is permeating the entire industry, it is believed that we can look forward hopefully toward a marked revival in the coal-tar products industry.

The Outlook in the Fertilizer Industry

The fertilizer business, emerging from the worst year in its history, has definitely turned the corner and is looking forward to better business conditions in 1922. This is the view expressed by a number of industrial leaders in an article appearing recently in the *Wall Street Journal.* Among the encouraging factors are the better inventory conditions, the reduction of bank loans, and finally the lower freight rates on fertilizer, effective Jan. 1.

The three leading factors in the trade, controlling as much as 55 per cent of the industry, suffered losses in operation for the first time in 60 years. Although this was primarily caused by the agricultural situation, one of the contributing causes was the large amounts charged to inventories for reduction in prices to market levels. For instance, the American Agricultural Chemical Co. absorbed in income account $5,022,731 for deductions on account of writing inventories down to market levels.

Russia Introduces the Metric System

According to a decree of the Peoples Commissars published in official Soviet papers, the metric system of measures has been introduced in all Soviet institutions beginning with January, 1922, and from 1924 the metric system of weights and measures must be finally and universally adopted throughout Soviet Russia.

New Schedule for Classification of Exports of Domestic Commodities

A new schedule governing the classification of exports of domestic commodities was put into effect Jan. 1 by the Bureau of Foreign and Domestic Commerce. In order that the new regulations in regard to statistical returns of exports may be carried into effect, J. Hohn, the chief of the bureau's division of statistics, points out that the co-operation of exporters is essential. It is absolutely necessary to the accuracy of the statistics that the shipper fill out his export declaration in accordance with the new classification.

Texas Leads in Oil Production

Texas is leading the country in petroleum production, and the different fields in the state are showing a strong tendency to increase present outputs. The Mexia field, one of the latest to be developed, has advanced from an average of 35,000 bbl. a day in November to more than 95,000 bbl. per day at the close of the year. Within 12 hours' travel from Dallas more than one-half the oil of the United States is now being produced. This includes the Mexia field, the Burkburnett district, averaging about 40,000 bbl. a day, and the Stephens County oil regions, with an output approximating 55,000 bbl. daily.

The London Market

From Our Special Correspondent

London, Dec. 17, 1921.

The general tone, both in financial circles and in chemical markets, is improving and decidedly optimistic, with a fairly brisk demand and a slight rise in the general level of prices. Acetone, formaldehyde, lithopone, sodium acetate and certain coal-tar intermediates have been in request, particularly for prompt delivery. It is expected that after the approaching stocktaking period there will be a gradual departure from the present unfortunate habit of buying from hand to mouth, and with the removal of anxiety in various directions as to payments of preference dividends, sound business seems in sight.

The New York Market

New York, Jan. 9, 1922.

The only trading of any importance in the chemical market during the past week was the contract transactions among leading manufacturers. Consumers have been purchasing for future delivery in better volume than at any period during 1921 and producers are inclined to believe that these signs mark the beginning of better times for the industry. Importations have been falling off because of rising prices abroad and consumers have hesitated to place any large tonnage orders with importers for fear of non-delivery. The exchange rates have been a big factor in keeping prices higher abroad as well as maintaining steady prices for spot stocks.

General Chemicals

Although trading in the spot market remained dormant, prices did not sag, but in general continued to be steady. Imported bleaching powder has had a rather evident effect on the market and the domestic producers have been forced to reduce prices to meet this competition. German bleach is quoted here at $1.80 per 100 lb. Domestic prices are around $2.25 per 100 lb. f.o.b. works. *Bichromate of soda* has remained steady for the past month, with spot quotations around 7¼c. per lb. and contract prices at 7¾c. Imported *magnesium sulphate*, technical, is quoted around $1.05 per 100 lb., with a possibility of shading on firm business. Makers quote $1.85 per 100 lb., but apparently are willing to consider lower prices. Importers of *barium chloride* have raised their prices and quotations range around $53 per ton ex-dock New York. Manufacturers of *sulphuric acid*, 66 deg., have reduced their figures to a basis of $16.50 per ton, tank cars, f.o.b. works. A larger volume of business has been reported at the newly reduced prices. Quotations on imported *arsenic* are higher for spot and shipment and prices range around 6c. per lb. for immediate shipment from Japan. Spot prices are higher at 6½c.@7c. per lb., according to brand. Prices of *caustic potash*, 88-92 per cent, on spot are being well maintained and holders are asking 6c. per lb., this figure representing the lowest possible price. Resale prices of *soda ash* and *caustic soda* were a trifle higher on spot, but contract quotations remained quotably unchanged. Imported *tartaric acid* was slightly cheaper on spot. U.S.P. crystals were offered at 25½c. per lb. Domestic producers still quote 32c. per lb., f.o.b. New York.

Coal-Tar Products

The coal-tar products market showed very little change during the past week. Second-hand merchants find difficulty in moving any stocks and producers are still patiently awaiting some definite action that might stir up the industry. Contract bookings have been very scarce for the new year and dealers are practically at a loss to quote intelligently in the absence of any real business. Refiners of *benzene* have advanced their prices 2c. per gal., owing to the acute scarcity of supplies and the heavy demand. Prices on c.p. benzene are now quoted at 29@35c. per gal. in tank cars and drums. The 90 per cent grade is proportionately higher at 27@32c. per gal. *Naphthalene* refiners have also raised their prices after holding quotations at 6½c. per lb. for the past month. Prices for contracts now range from 7½@8½c. per lb. for the flake, according to quantity, and 8½@9½c. for the ball, on the same basis. The demand has been very good in the past week, since resale dealers have been unable to offer any fair-sized quantities for forward deliveries.

The St. Louis Market

St. Louis, Mo., Jan. 7, 1922.

The chemical and drug market has closed one of the most uncertain years in its history. However, the conditions prevailing are far healthier and buying can again be resumed with more confidence. The market has been pretty well cleared of the small broker and second-hand dealer, which has been a constant annoyance during the year just closed, but the heavy importations still continue to be a disturbing element. Many prominent and leading factors prophesy a great expansion in business for this year, and it is hoped that their prophecies will not fall short.

Alkalis

The price on *caustic* has not changed since our last report, but the market is somewhat firmer. Several contracts were made here in the last few days extending over the year 1922 which would seem to indicate that the consumer believes that prices have reached bottom. While these contracts carry protection against decline, they are firm orders and for large quantities. Carload price for solid 76 per cent in drums is $3.40 per 100 lb., f.o.b. point of production, less than carlots $4.25 per 100 lb. in single drums, with slight decline on 10-drum lots. Flake 76 per cent in carlots is $4 per 100 lb., f.o.b. point of production, in drum lots $4.75@$5 per 100 lb. *Soda ash* is $2.90 per 100 lb., *bicarbonate of soda* $2.50 per 100 lb. and *sal soda* $2 per 100 lb. in less than carlots, with the market very inactive.

Special and General Chemicals

A decided improvement has been noted in the demand for *aqua ammonia*, 26 deg., since the reduction. *Bismuth salts* have been in continual demand for several months, and apparently there will not be the usual lull this season. *Bromides* are not moving to a great extent, but manage to keep up with previous months. There is very little demand for *cream of tartar* and the market is uninteresting. *Creosotes* continue to hold an active position. *Glycerine* is still advancing, latest quotations for contract prices being 16c. The market is well sold up, and producers are firmly in control. *Sulphur* continues to move slowly, but manages to hold its previous place at $2 per 100 lb. Apparently no

contract business is being done at present, only spot goods being used.

Acids

There is nothing of great importance to mention in connection with the heavy commercial mineral acids. There is a constant and regular demand and a slight increase is noticeable. There has not been much change in the *citric acid* situation, and if anything the demand is somewhat better. The demand for *acid carbolic*, medicinal grade, is increasing and factors are capable of handling big business. *Acid phosphoric sirupy* is very slow. *Tartaric acid* business is practically nil.

Vegetable Oils and Naval Stores

Castor oil continues firm, easily maintaining its new price of 13c. in drums. That price is being shaded slightly on contract business, but all spot goods is being held at above price. *Linseed oil* is advancing, keeping step with the flaxseed market, which is now very firm. Producers of linseed oil expect a tariff on imported goods, and predict an increase of 10c. per gal. with the passage of the tariff measure. Contract business for a further period than May is being refused at 67c. *Turpentine* has shown a slight advance, reaching 86c. in single barrels and 82c. in 5-bbl. lots.

Paint Materials

The paint industry continues optimistic and substantiates its views by some good-sized orders. *Barytes* remain nominal, with movement slightly increasing. The *lithopone* manufacturers expect to be active soon, although imported goods have somewhat disturbed the market. *Whiting* in carlots can be had at around $13, f.o.b. cars St. Louis, and at $15 in ton lots f.o.b. buyer's door.

The Iron and Steel Market

Pittsburgh, Jan. 6, 1922.

The steel market enters the new year in better condition than would have been predicted from the practically universal reports of dullness in trade circulated in December. Few mills closed over the holidays, and the mills in general seem to have order books that will carry them in January with a production similar to production in the last 3 months of the old year.

The personal equation of the mills, so to speak, appears to have changed. There have been times when the mills colored somewhat too brightly the picture they drew of the trade they were enjoying. Of late, it would appear, they are disposed to minimize their trade. Presumably this is an outcome of the strongly competitive conditions that have existed in the market for 5 or 6 months. Each mill is indisposed to give its competitors an exaggerated idea of the volume of business it has obtained, lest the other mills seek by more strenuous competition to equal the record.

Production of steel ingots was fairly uniform during the last 3 months of 1921 at a rate of about 23,000,000 tons a year. Appearances are that mills will closely approach this rate even in January, and possibly exceed it, while in February and March, on account of seasonal conditions, the rate is likely to be exceeded.

What may be regarded as fundamental commercial conditions had little to do with the fluctuations in operating rates of the steel mills in 1921. The liquidation of stocks was the chief factor, hence it may be assumed that with general business conditions no better than they have been in the past few months the steel industry would be called upon to operate indefinitely at a rate of about 23,000,000 tons, while any improvement at all in general conditions would cause this rate to be exceeded. A change in conditions whereby there would be more incentive to regular investment construction would be a great aid to steel demand. There has been much building in the United States in the past few months, but chiefly in garages and dwelling houses, which do not require much steel.

Such a change cannot be predicted for any time within the next few months. In more immediate prospect is a movement on the part of buyers to restore their stocks part way to normal, say to 70 per cent of what is considered necessary and desirable for the efficient conduct of business, whether the business be that of manufacturing wares made from steel or distributing steel from the jobbing warehouse. All buyers reduced stocks in 1921 to an absolute minimum, partly on account of business uncertainties, partly on account of doubt as to steel prices, and partly as a general measure to liquidate in preparation for making a fresh start.

Steel prices are now relatively stable and there is encouragement to buyers to restore stocks, at least partially. As a matter of fact some conservative but well-posted distributors began even in December to build up stocks. Such a restocking, if only to one-half of normal, would provide a very substantial tonnage of business for the steel industry temporarily, and might send the rate of ingot production up to 30,000,000 tons a year before April 1.

Steel Prices Steadier

As to steel prices, they are distinctly steadier, on the whole, than at any time for months. They have not advanced, nor are they at all likely to advance, but from the prices currently quoted as representing the market in general there are smaller concessions possible in the case of large and desirable orders than were possible some time ago. Last August, when openly quoted prices were materially higher than at present, the extreme prices were probably fully as low as extreme prices are today.

One cause of the greater stability at present undoubtedly is that mills have a more exact appraisal as to the possibilities of operating. Last summer and early fall there was a disposition to make large concessions to build up an order book and get the lower production costs that would come from a larger operation. Prices were quoted not on the basis of existing cost but on a prospective cost based on a problematical operation. Today the mills know just about what operating rate to expect, and realize that they cannot swell the rate materially by cutting prices. Hence their prospective cost can be estimated with a considerable degree of accuracy, and there is excellent reason for believing that no mill of any size will knowingly sell steel at less than the prospective cost of production. Profits, of course, are not being sought and in not a few cases a slight loss might be tolerated for the purpose of giving employment to the men.

The market in general, unchanged in the past couple of weeks, now stands substantially as follows: Bars, shapes and plates, 1.50c.; hoops, bands and hot-rolled strip, 2c.; plain wire, 2.25c.; wire nails, $2.50; standard steel pipe, 71 per cent basing discount; black sheets, 3c.; galvanized sheets, 4c.; tin plate, $4.75. The American Steel & Wire Co., on account of price cutting by independents, has reduced its price on cold-rolled strip, effective Jan. 1, from 3.75c. to 3.50c.

Pig Iron

Pig iron continues very dull, but a buying movement of some proportions in foundry iron is expected toward the latter part of the month. A recent sale of basic iron by a steel works interest at $18.25 valley is now accepted by merchant furnaces as representing current value, the market having previously been quotable nominal at $19 valley. Bessemer remains quotable at $20 valley, and foundry at $19.50@$20 valley.

Coke

Contracts for Connellsville furnace coke for first quarter have been made at from $3.50 down to $3.25, and the latter price can now be done by buyers. It is said in some quarters that those who paid $3.50 and $3.40 bought too soon.

Of considerable interest is a transaction between the Youngstown Sheet & Tube Co. and the Trumbull-Cliffs Furnace Co., involving a coke supply for the Trumbull-Cliffs furnace, Warren, Ohio, of about 18,000 tons a month. This is a requirement contract, predicated on whether the furnace operates, while the seller reserves the right to discontinue the arrangement if it needs the coke for its own furnaces. The price is equal to $2.90, Connellsville basis. The price was not competitive, it appears, but was made to justify the furnace being blown in.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

		Carlots	Less Carlots
Acetic anhydride	lb.	—	$0 40 – $0 45
Acetone	lb.	$0 12½ – $0 12¼	13 – 13½
Acid, acetic, 28 per cent	100 lbs.	2 50 – 2 60	2 65 – 3 00
Acetic, 56 per cent	100 lbs.	5 00 – 5 25	5 30 – 5 50
Acetic, glacial, 99½ per cent, carboys, 100 lbs.		10 00 – 10 50	10 75 – 11 00
Boric, crystals	lb.	12½ – 12⅝	13 – 13½
Boric, powder	lb.	12¼ – 13	13½ – 14
Citric	lb.	—	43 – 45
Hydrochloric	100 lb.	1 50 – 1 60	1 65 – 2 00
Hydrofluoric, 52 per cent	lb.	13 – 13¼	13½ – 14
Lactic, 44 per cent tech	lb.	09½ – 10	10½ – 12
Lactic, 22 per cent tech	lb.	04 – 04¼	04½ – 05
Molybdic, c.p.	lb.	3 00 – 3 25	3 30 – 3 75
Muriatic, 20 deg. (see hydrochloric)		—	—
Nitric, 40 deg.	lb.	06¼ – 06½	06⅔ – 07
Nitric, 42 deg.	lb.	06¾ – 07	07¼ – 07½
Oxalic, crys tals	lb.	14½ – 15	15½ – 16
Phosphoric, 50 per cent solution	lb.	11 – 11½	11¾ – 12½
Picric	lb.	20 – 25	27 – 35
Pyrogallic, resublimed	lb.	—	1 65 – 1 75
Sulphuric, 60 deg., tank cars	ton	—	11 00 – 12 00
Sulphuric, 60 deg., drums	ton	—	13 00 – 15.00
Sulphuric, 66 deg., tank cars	ton	16 50 – 17 00	—
Sulphuric, 66 deg., drums	ton	21 00 – 22 00	22 50 – 23.00
Sulphuric, 66 deg., carboys	ton	—	—
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	21 00 – 22 00	—
Sulphuric, fuming, 20 per cent (oleum) drums	ton	23 00 – 23 50	24 00 – 24 50
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31 00 – 32.00	33 00 – 34 00
Tannic, U. S. P	lb.	—	65 – 75
Tannic (tech.)	lb.	45 – 50	51 – 55
Tartaric, imported crystals	lb.	—	.25½ – .26
Tartaric acid, imported, powdered	lb.	—	.26 – .27
Tartaric acid, domestic	lb.	—	— .32
Tungstic, per lb. of WO	lb.	—	1 00 – 1 10
Alcohol, ethyl	gal.	—	4 75 – 5 00
Alcohol, methyl (see methanol)		—	—
Alcohol, denatured, 188 proof	gal.	—	42 – 43
Alcohol, denatured, 190 proof	gal.	—	43 – 44
Alum, ammonia, lump	lb.	03½ – .03¾	.04 – 04¼
Alum, potash, lump	lb.	03½ – .04	04¼ – 04½
Alum, chrome lump	lb.	08 – 08¼	08½ – 09
Aluminum sulphate, commercial	lb.	01¾ – 02	02½ – 02¾
Aluminum sulphate, iron free	lb.	02½ – 02¾	03 – 03¼
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	07½ – 07¾	08 – 08½
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	.30 – 30½	31 – 33
Ammonium carbonate, powder	lb.	.07 – 07½	08 – .09
Ammonium chloride, granular (white salammoniac)	lb.	.07 – .07¼	07½ – 07¾
Ammonium chloride, granular (gray salammoniac)	lb.	07 – 07¼	07½ – 07¾
Ammonium nitrate	lb.	07¼ – 07½	07⅔ – 08¼
Amylacetate tech	gal.	—	2 00 – 2 40
Arsenic oxide, (white arsenic) powdered	lb.	06¾ – 06¾	.07 – 07½
Arsenic, sulphide, powdered (red arsenic)	lb.	12 – 12¼	12⅔ – 13
Barium chloride	ton	51 00 – 52 00	53 00 – 60 00
Barium dioxide (peroxide)	lb.	21 – 21½	22 – .23
Barium nitrate	lb.	07 – 07½	.07¾ – .09
Barium sulphate (precip.) (blanc fixe)	lb.	03¾ – .04	04¼ – 04½
Blanc fixe, dry	lb.	04 – .04½	—
Blanc fixe, pulp	ton	45 00 – 55.00	—
Bleaching powder (see calc. hypochlorite)		—	—
Blue vitriol (see copper sulphate)		—	—
Borax (see sodium borate)		—	—
Brimstone (see sulphur, roll)		—	—
Bromine	lb.	21 – 22	23 – 28
Calcium acetate	100 lbs.	1 75 – 2 00	—
Calcium carbide	lb.	04½ – 04¾	.05 – 05½
Calcium chloride, fused, lump	ton	23.00 – 24 00	24 50 – 28 00
Calcium chloride, granulated	lb.	01¾ – .02	02¼ – 02½
Calcium hypochlorite (bleach'g powder)	100 lb.	2 50 – 2 60	2 65 – 3 25
Calcium peroxide	lb.	—	1 40 – 1 50
Calcium phosphate, tribasic	lb.	—	.15 – 16
Camphor	lb.	—	.90 – .95
Carbon bisulphide	lb.	06½ – 06¾	.07 – .07½
Carbon tetrachloride, drums	lb.	10½ – 10¼	.11 – .12
Carbonyl chloride, (phosgene)	lb.	—	60 – .75
Caustic potash (see potassium hydroxide)		—	—
Caustic soda (see sodium hydroxide)		—	—
Chalk, precip.—domestic, light	lb.	03¾ – .04	—
Chalk, precip.—domestic, heavy	lb.	03½ – 03¾	—
Chalk, precip.—imported, light	lb.	04 – 04½	—
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	06 – 06½	.06½ – .07
Chloroform	lb.	—	.38 – .40
Cobalt oxide	lb.	—	2 00 – 2 10
Copperas (see iron sulphate)		—	—
Copper carbonate, green precipitate	lb.	20 – 20½	21 – 21½
Copper cyanide	lb.	—	58 – 60
Copper sulphate, crystals	100 lb.	5.60 – 5 65	5 70 – 6 25
Cream of tartar (see potassium bitartrate)		—	—
Epsom salt (see magnesium sulphate)		—	—
Ethyl acetate com. 85%	gal.	—	60 – 70
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	—	95 –
Formaldehyde, 40 per cent	lb.	10½ – 10¾	11 – 12
Fullers earth, f.o.b. mines	net ton	16 00 – 17 00	—
Fullers earth—imported powdered—net	ton	30 00 – 32.00	—
Fusel oil, ref.	gal.	—	2 50 – 3 00
Fusel oil, crude	gal.	—	1 50 – 1 75
Glauber's salt (see sodium sulphate)		—	—
Glycerine, c. p. drums extra	lb.	—	.16 – 16½
Iodine, resublimed	lb.	—	3 80 – 3 90
Iron oxide, red	lb.	—	.12 – 18
Iron sulphate (copperas)	ton	15 00 – 16 00	17 00 – 20 00
Lead acetate	lb.	—	10¾ – 12½
Lead arsenate, powd	lb.	15 – 15½	15¾ – 16¾
Lead nitrate	lb.	—	15 – 20
Litharge	lb.	08 – .08¼	.08½ – 09
Magnesium carbonate, technical	lb.	06½ – 07	07¼ – 08
Magnesium sulphate, U. S. P.	100 lb.	2 65 – 2 70	2 75 – 3 00
Magnesium sulphate, technical	100 lb.	—	1 65 – 1 80
Methanol, 95%	gal.	—	.62 – .63
Methanol, 97%	gal.	$.... – $....	$0 64 – $0.65
Nickel salt, double	lb.	—	11 – 11½
Nickel salt, single	lb.	—	12 – 12¼
Phosgene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	45 – .46	47 – .50
Phosphorus, yellow	lb.	—	30 – 35
Potassium bichromate	lb.	10½ – .11	11¼ – 11½
Potassium bitartrate (cream of tartar)	lb.	—	.24 – .26
Potassium bromide, granular	lb.	—	.14 – .18
Potassium carbonate, U. S. P	lb.	.11 – .12	12½ – .15
Potassium carbonate, 80–85%	lb.	.04½ – .04¾	.05 – .06
Potassium chlorate, crystals	lb.	.05⅔ – .06	06¼ – .12
Potassium cyanide	lb.	—	43 – .45
Potassium hydroxide (caustic potash)	lb.	.06 – .06½	06½ – .06¾
Potassium iodide	lb.	—	2.90 – 3.00
Potassium nitrate	lb.	.07¼ – .07½	.08 – .09
Potassium permanganate	lb.	.15 – .16	16½ – .22
Potassium prussiate, red	lb.	.30 – 30½	.31 – .31½
Potassium prussiate, yellow	lb.	24½ – .24¾	.25 – .26
Rochelle salts (see sodium potas tartrate)		—	—
Salammoniac (see ammonium chloride)		—	—
Sal soda (see sodium carbonate)		—	—
Salt cake (bulk)	ton	—	18.00 – 21.00
Soda ash, light	100 lb.	1.85 – 2.10	2.15 – 2.50
Soda ash, dense	100 lb.	2.15 – 2.20	2.25 – 2.50
Sodium acetate	lb.	.04 – .04¼	.04½ – 05
Sodium bicarbonate	100 lb.	2.30 – 2.35	2.40 – 2.75
Sodium bichromate	lb.	.07⅞ – .08	.08¼ – .08½
Sodium bisulphate (nitre cake)	ton	5.00 – 5.25	5.50 – 6.50
Sodium bisulphite powdered, U.S.P.	lb.	.04¾ – .05	.05½ – .06
Sodium borate (borax)	lb.	.05½ – .06	.06½ – 07
Sodium carbonate (sal soda)	100 lb.	1.80 – 1.90	1.95 – 2.15
Sodium chlorate	lb.	.06½ – .07	.07½ – .08
Sodium chloride	long ton	12 00 – 13 00	—
Sodium cyanide	lb.	.26 – .26½	.26¾ – .27
Sodium fluoride	lb.	.10½ – .11	.11½ – .12
Sodium hydroxide (caustic soda)	100 lb.	3.80 – 3.85	3.90 – 4.30
Sodium hyposulphite	lb.	—	.03½ – .03¾
Sodium nitrite	lb.	.06⅝ – .06¾	07 – .07½
Sodium peroxide, powdered	lb.	.25 – .26	.27 – .30
Sodium phosphate, dibasic	lb.	.04¼ – .04½	.04¾ – .05¼
Sodium potassium tartrate (Rochelle salts)	lb.	—	.19 – .21
Sodium prussiate, yellow	lb.	.17 – .17½	.17¾ – .18
Sodium silicate, solution (40 deg.)	100 lb.	1.00 – 1.05	1.10 – 1.30
Sodium silicate, solution (60 deg.)	100 lb.	2.75 – 3.00	3.25 – 3.50
Sodium sulphate, crystals (glaubers salt)	100 lbs.	1.30 – 1.50	1.60 – 2.00
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04¼ – .04½	.04¾ – .05
Sodium sulphite, crystals	lb.	.03⅝ – .03¾	.04 – .04½
Strontium nitrate, powdered	lb.	.10 – .11	.11½ – .15
Sulphur chl ride, red	lb.	.05¼ – .05½	.05¾ – .06
Sulphur, crude	ton	18.00 – 20.00	—
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	—	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	—	2.00 – 2.75
Talc—imported	ton	30 00 – 40 00	—
Talc—domestic powdered	ton	18 00 – 25 00	—
Tin bichloride	lb.	.09 – .09½	.09¾ – .10
Tin oxide	lb.	—	.39 – .40
Zinc carbonate	lb.	.14 – .14½	.15 – .16
Zinc chloride, gran	lb.	.09 – .09¼	.09½ – .10
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc dust	lb.	.11¼ – .11½	.11¾ – .12½
Zinc oxide, XX	lb.	.07½ – .07¾	.08 – .09
Zinc sulphate	100 lb.	3.00 – 3.25	3.30 – 3.50

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.15 — 1.20
Alpha-naphthylamine	lb.	.30 — .32
Aniline oil, drums extra	lb.	.17 — .18
Aniline salts	lb.	.25 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.35 — 1.45
Benzidine, base	lb.	.90 — 1.00
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.70 — .75
Beta-naphthol, tech	lb.	.30 — .34
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)	lb.	.24 — .26
Cresylic acid, 97–99%, straw color, in drums	gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums	gal.	.65 — .70
Cresylic acid, 50%, first quality, drums	gal.	.45 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.90 — 1.05
Dimethylaniline	lb.	.40 — .45
Dinitrobenzene	lb.	.21 — 25
Dinitroclorbenzene	lb.	.25 — 27
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.38 — 40
Dinitrotoluene	lb.	.25 — 30
Dip oil, 25%, car lots, in drums	gal.	.31 — 35
Diphenylamine	lb.	.60 — .70
H-acid	lb.	1.00 — 1.10
Meta-phenylenediamine	lb.	1.10 — 1.15
Monochlorbenzene	lb.	.10 — .12
Monoethylaniline	lb.	1.40 — 1.45
Naphthalene crushed, in bbls.	lb.	.07 — .08
Naphthalene, flake	lb.	.07 — .08
Naphthalene, balls	lb.	.08 — .09
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.11 — .14
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	3.00 — 3.10
Ortho-dichlor-benzene	lb.	.15 — 20
Ortho-nitro-phenol	lb.	.75 — 80
Ortho-nitro-toluene	lb.	.15 — 20

Ortho-toluidine	lb.	.20 —	.25
Para-amidophenol, base	lb.	1.30 —	1.35
Para-amidophenol, HCl	lb.	1.60 —	1.70
Para-dichlorbenzene	lb.	.15 —	.17
Paranitroaniline	lb.	.77 —	.80
Para-nitrotoluene	lb.	.75 —	.80
Para-phenylenediamine	lb.	1.65 —	1.70
Para-toluidine	lb.	1.15 —	1.25
Phthalic anhydride	lb.	.37 —	.40
Phenol, U. S. P., drums	lb.	.11½ —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.50 —	1.60
Resorcinol, pure	lb.	2.00 —	2.25
Salicylic acid, tech., in bbls	lb.	.20 —	.21
Salicylic acid, U. S. P	lb.	.22 —	.23
Salol	lb.	.75 —	.77
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.16
Sulphanilic acid, crude	lb.	.26 —	.28
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.32 —	.38
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices are quotably unchanged for the entire list.

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$5.30 —	5.35
Rosin E-I	280 lb.	5.40 —	5.50
Rosin K-N	280 lb.	6.05 —	6.75
Rosin W. G.-W. W	280 lb.	7.00 —	7.25
Wood rosin, bbl	280 lb.	6.25 —	....
Spirits of turpentine	gal.	.82½ —	....
Wood turpentine, steam dist	gal.	.80 —	....
Wood turpentine, dest. dist	gal.	.79 —	....
Pine tar pitch, bbl	200 lb.	.... —	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	.... —	9.50
Retort tar, bbl	500 lb.	—	9.50
Rosin oil, first run	gal.	.36 —	....
Rosin oil, second run	gal.	.39 —	....
Rosin oil, third run	gal.	.46 —	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		$1.90
Pine oil, pure, dest. dist	gal.		1.50
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.35
Turpentine, crude, sp. gr., 0.900-0.970	gal.		1.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.35
Pinewood creosote, ref	gal.		.52

Fertilizers

Ammonium sulphate, bulk and double bags	100 lb.	$2.30 —	2.90
Blood, dried, f.o.b., N. Y	unit	4.00	
Bone, 3 and 50, ground, raw	ton	30.00 —	32.00
Fish scrap, dom., dried, f.o.b. works	unit	2.90 —	3.00
Nitrate soda	100 lb.	2.30 —	2.35
Tankage, high grade, f.o.b. Chicago	unit	2.75 —	3.00
Phosphate rock, f.o.b. mines, Florida pebble, 68-72%	ton	4.50 —	6.50
Tennessee, 78-80%	ton	8.50 —	9.00
Potassium muriate, 80%	ton	33.00 —	34.00
Potassium sulphate	unit	.95 —	1.00

Crude Rubber

Quotations have remained unchanged since our previous report.

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.10¼ —	$0.10¾
Castor oil, AA, in bbls	lb.	.11½ —	.12
China wood oil, in bbls. (f.o.b. Pac. coast)	lb.	.13¼ —	.13¾
Cocoanut oil, Ceylon grade, in bbls	lb.	.08½ —	.09
Coconut oil, Cochin grade, in bbls	lb.	.10 —	.10¼
Corn oil, crude, in bbls	lb.	.09 —	.09¼
Cottonseed oil, crude (f. o. b. mill)	lb.	.07 —	.07¼
Cottonseed oil, summer yellow	lb.	.08¼ —	.09
Cottonseed oil, winter yellow	lb.	.09½ —	.09¾
Linseed oil, raw, car lots (domestic)	gal.	.69 —	.70
Linseed oil, raw, tank cars (domestic)	gal.	.64 —	.65
Linseed oil, in 5-bbl lots (domestic)	gal.	.72 —	.73
Olive oil, denatured	gal.	$1.15 —	$1.20
Palm, Lagos	lb.	.07½ —	.07¾
Palm, Niger	lb.	.06½ —	.06¾
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08 —	.08¼
Peanut oil, refined, in bbls	lb.	.11 —	.11¼
Rapeseed oil, refined in bbls	gal.	.82 —	.83
Rapeseed oil, blown, in bbls	gal.	.88 —	.90
Soya bean oil (Manchurian), in bbls, N. Y	lb.	.08¾ —	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.07¼ —	....

FISH

Light pressed menhaden	gal.	$0.46 —	....
Yellow bleached menhaden	gal.	.48 —	....
White bleached menhaden	gal.	.50 —	....
Blown menhaden	gal.	.57 —	....

Miscellaneous Materials

Prices remain unchanged throughout the list.

Refractories

All prices remain the same as figures appearing in our Dec. 28 issue.

Ferro-Alloys

All f.o.b. Works

Ferrocarbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00 —	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.12 —	....
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.13 —	
Ferromanganese, 76-80% Mn, domestic	gross ton	58.00 —	60.00
Ferromanganese, 76-80% Mn, Foreign, c. i. f. Atlantic seaport	gross ton	54.00 —	58.35
Spiegelcisen, 18-22% Mn	gross ton	25.00 —	27.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.25 —	....
Ferrosilicon, 10-15%	gross ton	38.00 —	40.00
Ferrosilicon, 50%	gross ton	57.00 —	59.00
Ferrosilicon, 75%	gross ton	120.00 —	125.00
Ferrotungsten, 70-80%, per lb. of contained W	lb.	.40 —	.45
Ferro-uranium, 35-50% of U, per lb. of U content	lb.	6.00 —	....
Ferrovanadium, 30-40% per lb. of contained V	lb.	4.25 —	4.50

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content	net ton	$8.00 —	$10.00
Chrome ore, Calif. concentrates, 50% min. Cr_2O_3	ton	22.00 —	23.00
Chrome ore, 50% Cr_2O_3, f.o.b. Atlantic seaboard	ton	22.00 —	23.00
Coke, foundry, f.o.b. ovens	net ton	4.25 —	4.50
Coke, furnace, f.o.b. ovens	net ton	3.25 —	3.50
Fluorspar, gravel, f.o.b. mines, New Mexico	net ton	12.00 —	....
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines	net ton	20.00 —	22.00
Ilmenite, 52% TiO_2, per lb. ore	lb.	.01¼ —	.01½
Manganese ore, 50% Mn, c.i.f. Atlantic seaport	unit	.23 —	.24
Manganese ore, chemical (MnO_2)	net ton	55.00 —	60.00
Molybdenite, 85% MoS_2, per lb. of MoS_2, N. Y	lb.	.45 —	.50
Monazite, per unit of ThO_2, c.i.f., Atlantic seaport	unit	30.00 —	....
Pyrites, Spanish, fines, c.i.f., Atlantic seaport	unit	.12 —	.12
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport	unit	.13 —	.13
Pyrites, domestic, fines, f.o.b. mines, Ga	unit	.11 —	.12
Rutile, 95% TiO_2 per lb. ore	lb.	.15 —	....
Tungsten, scheelite, 60% WO_3 and over, per unit of WO_3 (nominal)	unit	2.50 —	2.75
Tungsten, wolframite, 60% WO_3 and over, per unit of WO_3, N. Y. C	unit	2.75 —	3.00
Uranium ore (carnotite) per lb. of U_3O_8	lb.	1.25 —	1.75
Uranium oxide, 96% per lb. contained U_3O_8	lb.	2.25 —	2.50
Vanadium pentoxide, 99%	lb.	12.00 —	14.00
Vanadium ore, per lb. of V_2O_5 contained	lb.	1.00 —	....
Zircon, washed, iron free, f.o.b. Pablo, Florida	lb.	.04½ —	.13¼

Non-Ferrous Metals

New York Markets

	Cents per Lb

FINISHED METAL PRODUCTS AND OLD METALS

Quotations have remained unchanged since our previous report.

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Cleveland	Chicago
Structural shapes	$2.78	$2.88	$2.78
Soft steel bars	2.68	2.78	2.68
Soft steel bar shapes	2.68	2.78	2.68
Soft steel bands	3.28	3.48	3.28
Plates, ¼ to 1 in. thick	2.78	2.88	2.78

*Add 15c per 100 lb for trucking to Jersey City and 10c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Great Southern Steel Co., Chicago, Ill., recently organized with a capital of $105,000,000 under Delaware laws, has plans in preparation for the erection of a new steel plant at Birmingham, estimated to cost about $500,000 for initial units. The company, also, has about 10,000 acres of iron ore and coal properties in Etowah County and neighboring counties of Alabama, and purposes extensive development and operation of the lands. John W. Baker, 711 Lumber Exchange Bldg., Chicago, is one of the principals in the organization.

ALBANY—A. G. Patterson, Albany, and associates have plans under way for the development of a large tract of asphalt deposits, recently acquired. A plant will be installed.

California

NATIONAL CITY—The California Gypsum Co. has made application to the State Harbor Commission for a lease of tideland property at National City, totaling about 40 acres, to be used as a site for a new plant for the manufacture of gypsum products, estimated to cost approximately $250,000.

Colorado

FORT COLLINS—Fire, Dec. 22, destroyed the chemical building at the State Agricultural College here, with loss estimated at about $60,000.

Connecticut

NEW HAVEN—The Seamless Rubber Co., manufacturer of small rubber goods, has awarded a contract to the Dwight Building Co., 67 Church St., for the rebuilding of the portion of its plant, recently destroyed by fire, with loss estimated at $200,000, including equipment. The new structure will be located on Hallock Ave.

BRIDGEPORT—The D. & C. Oil Co., Lindley St., has awarded a contract to George Lyelos, 220 Parrott Ave., for the erection of its new plant on Colonial Ave., estimated to cost about $25,000.

Florida

DAYTONA—W. K. Tavel and H. B. Schulte, Daytona, are organizing a new company for the establishment of a local plant for the manufacture of cement brick, shingles and kindred specialties.

MIAMI—The Pennsylvania Sugar Co., 135 South Second St., Philadelphia, Pa., has awarded a building contract for the erection of the first unit of its proposed new sugar mill on property recently acquired near Miami. The plant will have an initial output of about 1,500 tons of cane sugar per day, and is estimated to cost close to $500,000.

LEESBURG—The Leesburg Pulp Mill Co. is considering preliminary plans for the doubling of its present plant capacity.

TAMPA—The Florida Nu-Tex Brick Co., 109 Water St., is planning for the establishment of a number of branch plants in different sections of the state for the manufacture of cement brick. W. B. Coarsey is president.

MOORE HAVEN—The Moore Haven Sugar Corp. is installing additional machinery at its mill and will begin operations under increased production within a few weeks. This is the first mill of this kind to be established in the Everglades section of the state.

PENSACOLA—The Southern Paving Co. is considering plans for extensions and improvements in its wood-block creosoting plant, to include the installation of tanks and other equipment, estimated to cost about $40,000.

Indiana

MARION—The Mileage Oil & Refining Co., Kokomo, Ind., has acquired the property of the Service Oil Co., Marion, at a receiver's sale, for a total consideration said to be $400,000. The new owner will operate the plant as an extension to present activities.

Kentucky

LOUISVILLE—The Standard Sanitary Mfg. Co., Bessemer Bldg., Pittsburgh, Pa., has awarded a contract to the George Rommell Co., 956 Logan St., Louisville, for the erection of a 1-story addition to its local pant at Sixth and A Sts., to be equipped as an enameling works. It is estimated to cost about $100,000. O. P. Ward, Lincoln Trust Bldg., Louisville, is architect.

Louisiana

ALEXANDRIA—The Alexandria Refining Co. has taken out a state charter with capital of $50,000, to construct and operate a local oil refinery. Erection of the new plant has been commenced. H. T. Clark is president, and G. W. Zodar, vice-president.

Maryland

HAGERSTOWN — The Bostwick - Lyon Bronze Co., Waynesport, Pa., operating a plant at Hagerstown under the name of the Hagerstown Bearing Metal Works, has acquired the local plant of the Maryland Smelting & Refining Co., and will merge the property with the Hagerstown works. Extensive operatons are planned.

Massachusetts

LOEMINSTER—The Viscoloid Co., Lancaster St., manufacturer of celluloid products, will soon commence the erection of a 2-story plant addition, 40 x 50 ft. The building contract has been let to the Wiley & Foss Co., Fitchburg, Mass.

ARLINGTON—The Frost Insecticide Co. has completed plans and will soon commence the erection of a new plant unit, estimated to cost about $40,000, including equipment.

Missouri

KANSAS CITY—The Hydro-United Tire Co., Pottstown, Pa., has acquired a controlling interest in the A. J. Stephens Rubber Co., with plant at Kansas City, and plan for increased operations at the works. J. H. Phillips is president of the Hydro-United company.

Montana

GREAT FALLS—The local Commercial Club is developing plants for the organization of a new company, to construct and operate a beet sugar manufacturing plant.

New Jersey

NEWARK—The Gulf Refining Co., Doremus Ave. near the Plank Road, has had plans prepared for the erection of a 1-story, reinforced-concrete machine shop at its local oil plant, 100 x 230 ft., estimated to cost about $70,000. Headquarters of the company are at 21 State St., New York.

New York

BROOKLYN—The P. L. Andrews Corp., 45 Irving Ave., manufacturer of envelopes and other paper products, has awarded a contract to the Caye Construction Co., 356 Fulton St., for the erection of a new 2-story plant, 55 x 100 ft., on Jefferson St., estimated to cost about $75,000.

Pennsylvania

SPRING GROVE—The P. H. Glatfelter Co., operating a local paper mill, has completed plans for increasing the capacity of the plant from 50 to 100 tons per day. An extension will be erected to provide for the installation of a new 168-in. machine and other finishing machinery.

ELIZABETHTOWN—The Farmers' Fertilizer Works, William Schneitman, head, is considering the erection of a new 1-story plant for the manufacture of commercial fertilizers.

NEW CUMBERLAND — E. E. Fleurie, Fifth and Reno Sts., is planning for the immediate rebuilding of his brick-manufacturing plant, destroyed by fire, Dec. 23, with loss estimated at about $25,000. New machinery will be installed.

PITTSBURGH — The H. J. Heinz Co., Progress St., manufacturer of canned food products, has plans in preparation for the erection of a 2-story and basement laboratory building, 40 x 100 ft. Bids will be asked and construction inaugurated at an early date.

Tennessee

GRAYSVILLE—The Dixie Coal, Lime & Clay Products Co., Chattanooga, Tenn., has acquired clay properties in the vicinity of Graysville, totaling about 400 acres, and plans for the installation of a clay-mining plant. It is also proposed to establish a works for the manufacture of firebrick and other burned clay products. The acquisition includes a large tract of lime deposits and a plant will be established for this development.

WHITE PINE — G. M. Felmet, White Pine, and associates, are organizing a new company to construct and operate a local flour mill. Plans are being prepared for a 4-story and basement mill, 36 x 70 ft., and ground will be broken early in the spring. The W. J. Savage Co., 912 West Church St., Knoxville, Tenn., is architect.

Texas

HOUSTON—The Humphreys-Pure Oil Co. interests have organized under Delaware laws the Humphreys-Pure Oil Refineries Corp., with capital of $50,000,000. The new organization will operate in the Mexia, Tex., oil fields, and plans for the erection of a new oil refinery in the vicinity of Houston, with output of about 30,000 bbl. of oil per day. A pipe line will be constructed from the Mexia district to a point on the Gulf, provided with a series of pumping stations and other operating equipment. The entire project is estimated to cost close to $5,000,000. Col. E. A. Humphreys heads the company.

NEWCASTLE—The Common Council is perfecting plans for the construction of a new filtration plant at the municipal waterworks. The Henry, Exall, Elrod Co., Dallas, Tex., is engineer.

AMARILLO—The Amarillo Brick & Tile Co. is establishing a plant in the vicinity of clay properties about 6 miles from Amarillo, and will inaugurate operations at an early date.

McGREGOR — The Koury Calcium Co., recently organized with a capital of $400,000, has acquired the plant and property of the Lone Star Co. at Oglesby, near Waco, consisting of about 360 acres of lime lands, with plant equipped for an output of about 1,000 bbl. of lime per day. The new owner purposes to operate the plant and develop an extensive output of raw material. The company will also begin operations at an early date on its properties near McGregor, recently acquired, with proposed plant at this location estimated to cost close to $100,000. Michael Koury is president, and W. V. Hanover, secretary.

HOUSTON—The Texas Co. has started preliminary work at its sulphur deposits at Haskins Mound, Tex., and has blocked out an area to provide for an output of over 10,000,000 tons. It is said that plans are being perfected for the organization of a subsidiary company, to be capitalized at $5,000,000, for the operation of the lands, and to construct a large plant in this vicinity. Considerable equipment will be purchased for installation.

Virginia

RICHMOND—The Manchester Board & Paper Co., West Canal St., is planning for extensions and improvements in its plant to cost about $15,000.

CHARLOTTESVILLE—The City Council has plans under way for the installation of a new filtration plant on Observatory Mountain for the waterworks system, estimated to cost about $130,000. Williamson, Carroll & Saunders, Charlottesville, are engineers.

West Virginia

HUNTINGTON—The International Nickel Co., 67 Wall St., New York, is maintaining active construction on its new local plant, which is now more than 50 per cent completed. The works comprise a refinery and rolling mill, and will be used primarily for the manufacture of Monel metal products. It is intended to have the plant ready for operation early in May. W. L. Wotherspoon, company address, is engineer.

Wisconsin

APPLETON—The Appleton Coated Paper Co. has broken ground for the erection of a new 3-story and basement building at its plant, estimated to cost about $35,000. Charles Boyd is manager.

Capital Increases, Etc.

THE FLINT VARNISH & COLOR WORKS, Flint, Mich., has filed notice of increase of capital from $1,500,000 to $3,500,000.

THE HOOKER ELECTROCHEMICAL CO., 25 Pine St., New York, N. Y., with plant at Niagara Falls, N. Y., has disposed of a bond issue of $1,250,000, the proceeds to be used for general financing, operations, etc.

THE INLAND METALS REFINING CO., 4837 South May St., Chicago, Ill., has filed notice of dissolution under state laws.

THE NATIONAL CARBIDE CORP., a Virginia corporation, has filed notice of intention to operate in New York, with capital of $350,000. E. V. O'Daniel, 342 Madison Ave., New York, is representative.

THE VERSAILLES SANITARY FIBRE MILLS, INC., Sprague, Conn., has filed notice of increase in capital from $300,000 to $500,000.

THE AMERICAN SUGAR REFINING CO., 117 Wall St., New York, has arranged for a bond issue of $30,000,000, the proceeds to be used for general financing, operations, etc.

THE GRANDFIELD OIL & REFINING CO., Grandfield, Okla., has filed notice of increase in capital from $125,000 to $300,000 for proposed expansion.

THE ECONOMY PAPER CO., 847 Broad St., Newark, N. J., has filed notice of increase in capital from $6,000 to $125,000 for general expansion.

THE UNION CHARCOAL & CHEMICAL CO., a Delaware corporation, has filed notice of intention to operate in New York, with capital of $250,000. C. M. Hancock, Olean, N. Y., is representative.

THE FEDERAL MICA CO., 217 Center St., New York, N. Y., has filed notice of dissolution under state laws.

New Companies

THE SOUTH HAVEN CHEMICAL CO., South Haven, Mich., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are J. C. Randall, J. C. Johnston and John C. Hunt, all of South Haven.

THE C. B. CASTLE CORP., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture oils, greases, etc. The incorporators are W. W. Heaton, W. B. Seawell and J. K. Berry. The company is represented by Porter & Taylor, 30 Broad St., New York.

THE CHEMICAL CONVERTING CO., 15 Exchange Pl., Jersey City, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are Martin J. Connolly, Edward F. Johnston and Paul Henderson.

THE JOHNSON OIL REFINING CO., 208 South La Salle St., Chicago, Ill., has been incorporated with a capital of $2,000,000, to manufacture petroleum products. The incorporators are G. C. Lilly, I. H. and Homer H. Johnson.

THE GOOCH, OTIS CO., INC., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture leather products. Albert N. Gooch is president, and Walter I. Otis, Everett, Mass., treasurer.

THE INSULATING PRODUCTS CO., Kalamazoo, Mich., has been incorporated with a capital of $25,000, to manufacture insulating specialties, pipe coverings and kindred products. The incorporators are Bailey A. Wright, Fred W. Myers and Donald P. Osborne, all of Kalamazoo.

THE RODIAN ELECTRO-METALLURGICAL CO., INC., Wilmington, Del., has been incorporated under state laws with capital of $10,000,000, to manufacture various metallurgical products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE ADVANCE CHEMICAL MFG. CO., 2756 Diversey Ave., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture chemicals, compounds, etc. The incorporators are Jacob Kaplan and Samuel L. Steinberg.

THE J. K. McIVER CO., Savannah, Ga., has been organized under state laws to manufacture fertilizer products. The company is headed by J. K. McIver and Bleecker P. Seaman, both of Savannah.

THE RUBBER PRODUCTS CO., Morgantown, W. Va., has been incorporated with a capital of $50,000, to manufacture rubber specialties. The incorporators are Earl Pepper, M. J. Melamphy, Jr., and C. W. Huston, all of Morgantown.

THE PRO-RALGIA CHEMICAL CO., Pittsburgh, Pa., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. H. A. Hauser, 323 Bailey Avenue, is treasurer.

THE LYNN IRON FOUNDRY, INC., Lynn, Mass., has been incorporated with a capital of $20,000, to manufacture iron, steel and other metal castings. Telesphor Mailloux is president; and I. George Pelletier, Salem, Mass., treasurer.

THE U. N. S. PAPER BOX CO., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture paper boxes and kindred products. The incorporators are R. Benrey, S. Redler and D. Crespi. The company is represented by W. R. Altman, 277 Broadway, New York.

THE SILVER REDUCTION CO., 155 North Clark St., Chicago, Ill., has been incorporated with a capital of $20,000, to manufacture metal products. The incorporators are Emerson B. Stoddard, Charles E. Johnson and Ralph E. Rich.

THE DURAND-WILCOX GLASS CO., Newfield, N. J., has been incorporated with a capital of $100,000, to manufacture glass products of various kinds. The incorporators are M. D. and Victor Durand, Jr., and Albert C. Wilcox, all of Newfield.

THE AMERICAN EAGLE OIL CO., Taft, Cal., has been incorporated with a capital of $500,000, to manufacture petroleum products. The incorporators are J. B. Baker, O. R. Tucker, A. S. Johnston and R. E. Havenstrite, all of Taft.

THE MARYLAND FELT & PAPER CO., Calvert Bldg., 101 East Fayette St., Baltimore, Md., has been incorporated with a capital of $1,000,000, to manufacture paper and other kindred products. The incorporators are Joseph P. Murray, Frank S. Muzzey, and P. Stanley Saurman.

THE CONRAD FOUNDRY CO., 615 Montgomery Ave., Elizabeth, N. J., has been incorporated with a capital of $100,000, to manufacture steel, iron and other metal castings. The incorporators are John F. Conrad, William R. Miller and John Ebel.

THE TRUTEST CHEMICAL CORP., Wilmington, Del., has been incorporated under state laws with capital of $500,000, to manufacture chemicals, compounds etc. The company is represented by the Corporation Service Co., Wilmington.

THE SAN CHEMICAL CO., Columbia, S. C., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. J. S. Hammoch is president and treasurer; J. B. Pratt, vice-president; and E. H. Salmon, secretary, all of Columbia.

THE ESSEX CHEMICAL & SPECIALTY CO., Newark, N. J., has been incorporated with a capital of $50,000, to manufacture chemicals, compounds, etc. The incorporators are Emanuel P. Scheck, I. V. Davis and Harry E. Young, 790 Broad St., Newark.

THE STORAGE PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture cement, asphalt and kindred products. The incorporators are S. D. Joseph, A. M. Steinberg and B. Mayer. The company is represented by E. Enselman, 220 Broadway, New York.

THE SURE LIFE PRODUCTS CO., Wilmington, Del., has been incorporated under state laws with capital of $250,000, to manufacture polishes, dyes and kindred chemical specialties. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE VALLEY TILE & CONCRETE CO., San Benito, Tex., has been incorporated with a capital of $10,000, to manufacture cement tile and kindred specialties. G. W. Wilkerson, San Benito, is president.

THE COMANCHE POINT OIL CO., Los Angeles, Cal., has been incorporated with a capital of $1,000,000, to manufacture petroleum products. The incorporators are J. S. Farrow, B. S. Hunter, J. N. Kerwin and Glenn N. Deuel. The company is represented by Benjamin S. Hunter, Citizens' National Bank Bldg., Los Angeles.

THE PENNSYLVANIA SOAP CO., Pittsburgh, Pa., has been incorporated under Delaware laws, with capital of $250,000, to manufacture soaps and kindred products. The incorporators are Arthur C. Volbrecht, Louis A. Snyder. The company is represented by the Capital Trust Co. of Delaware, Dover, Del.

THE OSANTOS CHEMICAL CO., 110 South Dearborn St., Chicago, Ill., has been incorporated with a capital of 400 shares of stock, no par value, to manufacture chemical compounds, etc. The incorporators are A. M. Domber, F. W. Metz and Thomas S. Milcarek.

THE KNOXVILLE CEMENT PRODUCTS CO., Oakwood, near Carbondale, Tenn., has been incorporated with a capital of $10,000, to manufacture cement specialties. The incorporators are Chester Koehn, Harmon Austin and Charles A. Russell, Oakwood.

THE SENSO MFG. CO., Fort Wayne, Ind., has been incorporated with a capital of $10,000, to manufacture chemical compounds, disinfectants, etc. The incorporators are C. J. Shimer, R. J. Brown and J. C. Beyer.

THE HAGMAYER CHEMICAL & MFG. CO., Philadelphia, Pa., has been incorporated under Delaware laws, with a capital of $100,000, to manufacture chemicals, paints, etc. The company is represented by the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia.

THE TRENTON CHEMICAL CO., Trenton, N. J., has been organized under state laws to manufacture chemicals and chemical byproducts. The company is headed by F. Walter Messler and M. L. Ward Suydam, 1109 Division St., Trenton.

THE SOUTHERN PACIFIC BRICK & TILE CO., Fresno, Cal., has been incorporated with a capital of $250,000, to manufacture brick, tile and other burned clay products. The incorporators are W. H. Shields, Fresno; W. D. Trewhitt, Hanford, Cal.; and L. E. Hayes, Exeter, Cal.

THE PHOENIX CHEMICAL WORKS, INC., Houston, Tex., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are John Pfeiffer, E. J. Blunt and M. H. Webster, Houston.

THE SHOPE BRICK CO., Springfield, Mass., has been incorporated with a capital of $125,000, to manufacture brick, tile and other burned clay products. William J. Kressler is president; Paul G. Seyler, vice-president; and Edward F. Seyler, treasurer, all of Springfield.

Manufacturers' Catalogs

W. S. ROCKWELL CO., New York, has just issued Bulletin 234, on "The Continuous Heat-Treatment of Metals With Automatic and Semi-Automatic Furnaces," which is the fourth of the series dealing with fundamentals that influence the quality and cost of heated products. This bulletin illustrates practical applications of the principles outlined by the previous bulletins of this series—namely, Nos. 230, 231 and 232. Attention is also called to Bull. 239, which relates to an improved type of forge furnace. The novel features of the furnace consist of means for better application of the heat, protection of the operator, and utilization of waste gases to preheat air and fuel for combustion.

THE ALBERGER CHEMICAL MACHINERY CO., New York, has issued Bulletins 34 and 36, on the Nelson filter presses and Alberger vertical mixers.

THE ENGINEERING MAGAZINE CO., New York City, in November, started publication of a new magazine known as *Industry Illustrated*.

THE STURTEVANT MILL CO., Boston, Mass., has made a new departure in the production of a catalog showing the use of Sturtevant equipment in the fertilizer industry. It has published a pretentious treatise entitled "The Modern Fertilizer Plant," covering every step in the production of fertilizer from rock phosphates. From the time the phosphate rock is received in box cars, from which it is removed by a power shovel, to the mechanical sacking and shipping of the finished product, every intermediate step is described and illustrated. Unquestionably this is one of the most complete treatments of an industrial process that has been covered in catalog form.

THE WHEELER CONDENSER & ENGINEERING CO., Carteret, N. J., has issued a new catalog on centrifugal pumps, catalog 108-C, which described construction details and fully illustrates the application of high-efficiency double suction pumps for every purpose. Single-stage horizontal and vertical shaft pumps and multi-rotor pumps are included. Of special interest are the illustrations of circulating pumps for condensers of all sizes. Several types are also shown for each of the other usual pumping services, many of special and unusual design. Methods are given for constructing the characteristic curves of a centrifugal pump at varying speeds where the characteristics are known for constant speed operation. Instructions are given for installing and operating centrifugal pumps and also many useful data for making calculations and writing specifications.

THE ELECTRO-REFRACTORIES CORP., Ellicott Sq., Buffalo, has issued a circular describing its new Tercod crucible which gives a list of the particular advantages such as high-conductivity, non-scalping, non-scaling, clean-pouring, etc.

Industrial Notes

THE RUBBER SERVICE LABORATORIES Co. appears in the list of new Ohio corporations. The incorporators are given as R. C. Hartong, C. W. Bedford, C. O. North and C. N. Hand, all formerly connected with the development department of the Goodyear Tire & Rubber Co. This concern will manufacture organic accelerators and other materials for the rubber trade and furnish free consultation service with its products, offering its entire staff for consultation, development and routine service to rubber and related industries. It will function as an auxiliary department to supplement the existing staff of its clients or to furnish such service to small rubber companies which do not maintain development departments. This service will be rendered on a highly ethical basis. It is not the policy of this company to "peddle formulas" or to disclose the secrets of its clients. It will develop formulas for specific uses or improve existing compounds, install new processes or modify old ones and aid in the development of suitable materials for the rubber trade in general. Manufacturers of raw materials, such as pigments, fillers or fluxes, will be interested in the availability of the service of this company. Many smaller rubber companies, and especially those just starting in the rubber business, will likewise welcome the prospect of obtaining expert advice without increase of overhead costs.

THE SEYMOUR CHEMICAL Co., Mount Morris, N. Y., at its recent annual meeting elected Howard I. Averill president. Other officers elected were: O. B. Dow, vice-president; W. T. Larkin, secretary and treasurer, and L. C. Donovan, foreman.

THE AMERICAN VITRIFIED CHINA MANUFACTURERS, East Liverpool, O., at its recent annual meeting elected the following officers for the ensuing year: President, C. E. Jackson, head of the Warwick China Co., Wheeling, W. Va.; vice-president, D. William Scammell, Maddock Pottery Co., Trenton, N. J.; secretary and treasurer, Arthur E. Mayer, head of the Mayer China Co., Beaver Falls, Pa.

THE DU PONT Co., of Wilmington, Del., at its recent stockholders meeting elected the following directors: H. F. Brown, H. E. Lackey, J. W. Elms, F. B. Davis, Jr., Hunter Grubb, W. F. Rascob, Fin Sparre and Clifford McIntyre.

THE STANDARD BRICK & TILE Co., Portland, Ore., has elected A. H. Wethey, Jr., president. Otis J. Fitch has been appointed sales manager for the company.

R. E. Clarke, formerly vice-president of the Seaboard Oil Co., New York, and F. W. Steadman, previously connected with the Carson Petroleum Co., have organized a new company under the name of CLARKE & STEADMAN, to engage in the oil business. Offices have been established in the Produce Exchange Bldg.

THE NICKLE ENGINEERING WORKS, Saginaw, Mich., manufacturer of agitator equipment for chemical tanks, has leased a portion of the Schemm Brewing Co. plant, 920 North Hamilton St., for machine shop purposes.

THE AMERICAN CREOSOTING Co., Louisville, Ky., is erecting a new plant for timber preserving at New Haven, Conn. This plant consists of a retort house with two cylinders 7 ft. in diameter and 150 ft. long, with the necessary pumping machinery and other required equipment. The boiler house will be a modern type of 600-boiler horsepower. In addition there will be large tie handling facilities. Contract arrangements have been entered into for the building of the plant and construction is now under way. The plant will be the last word in engineering design for tie treating. The product will be used chiefly by the New York, New Haven & Hartford R.R.

THE UNIFORM ADHESIVE Co., Brooklyn, N. Y., is now operating its new plant at Bush Terminal, producing glues, gums, pastes and adhesives. Dr. Jerome Alexander is president and Walter Alexander, vice-president.

THE QUIGLEY FURNACE SPECIALTIES Co., New York City, announces that it will be represented in the Chicago territory by H. M. Thompson, who was formerly identified with the Thomas Moulding Brick Co., who succeeds Bell & Gossett, former agents. Mr. Thompson will make his headquarters at 105 West Monroe Street, Chicago. It is also announced that the Federal Supply Co., East 79th Street, Cleveland, O., have been appointed representatives in that territory.

THE GREEN ENGINEERING Co., East Chicago, Ind., announces the opening of a direct branch sales office in suit 941, Monadnock Bldg., Chicago, Ill. The former agency representation has been discontinued in the Chicago district. J. W. Himmelsbach has been appointed district manager. P. Albert Poppenhusen, president of the company, will maintain an office at the Chicago address, while the general sales office will remain at the factory.

THE WILSON WELDER & METALS Co. announces the removal of its general offices and Bush Terminal factory to 132 King St., New York City. This company announces that the change has increased its facilities for service in certified plastic arc-welding metals by the installation of improved equipment.

THE CUTLER-HAMMER MFG. Co. has moved its Boston office from the Columbian Life Bldg. to Rooms 403 and 404, Harvey Bldg., Chancy St. C. W. Yerger is manager.

THE COMBUSTION ENGINEERING CORP. has opened a new branch office at 806 First National Bank Bldg., Pittsburgh, Pa., which will be in charge of W. C. Stripe, formerly manager of the Philadelphia office.

H. L. DICK, Chicago manager for Emil E. Lungwitz, has returned to Chicago after a six months' stay at the New York office of the company.

WESTINGHOUSE, CHURCH, KERR & Co.'s employees, to the number of 140, recently organized the "W. C. K. Association." The object of this organization is the maintenance of the friendship formed by its members during their years of service with Westinghouse, Church, Kerr & Co. The association meets every Wednesday for lunch between 12 and 1 o'clock at Zimmermann's restaurant, 108 Fulton St., New York City. The secretary, A. H. Tummel, 131 Warwick St., Brooklyn, N. Y., will be glad to hear from former employees who desire to join the association.

THE EXETER MACHINE WORKS, INC., West Pittston, Pa., has appointed J. E. Holveck district sales representative in the Pittsburgh district. Mr. Holveck was until recently connected with Crawford & Cameron of Pittsburgh, and was formerly designing engineer for the Aldrich Pump Co. of Allentown, Pa. This company also announces the appointment of the Allen Engineering Co. as sales agent for the Exeter rotary pump line in the Boston district.

THE ENGINEERING ADVERTISERS' ASSOCIATION of Chicago is now publishing a monthly bulletin in the interest of its members, giving a digest of the speeches made at the various meetings and other information and facts regarding the movement of goods from industry to industry, personal notes, etc. A limited number of extra copies of the "Bulletin" will be sent upon request to the advertising manager of concerns selling technical or engineering products.

THE MAHER ENGINEERING Co., Chicago, announces that C. B. Adams has been appointed vice-president and sales manager and C. H. Peterson has been appointed secretary-treasurer and general manager.

ALFRED M. BEST Co., insurance and advisory service, New York, announces the appointment of E. H. Seaman to take charge of its advisory and engineering departments. Mr. Seaman will direct all operations in the Eastern and Southern fields and will devote special attention to industrial plants with a view to reducing industrial waste and cost of insurance. He has specialized in fire protection and prevention for over 15 years in the United States and Canada.

The executors of the estate of JOHN C. WIARDA have sold the assets of the chemical manufacturing and jobbing business at 273 Green St., Brooklyn, N. Y., to Howard B. Bishop of 101 Park Ave., New York. Mr. Bishop is a chemical engineer and was for many years connected with the General Chemical Co. and the National Aniline & Chemical Co. The new management will continue the business under the name of John C. Wiarda & Co., Inc., and will enlarge and extend its manufacturing and jobbing facilities.

THE PITTSBURGH ELECTRIC FURNACE CORP., Pittsburgh, Pa., announces that A. D. Keene, formerly electric furnace engineer of the General Electric Co., Schenectady, N. Y., is now connected with it as engineer on electric furnace designs and applications in the steel and metal industries. Mr. Keene has moved his residence from Schenectady to Pittsburgh, Pa.

THE UNITED CHEMICAL & ORGANIC PRODUCTS Co., formerly at 217 Broadway, have moved to larger quarters at 401 East 45th St., New York City.

THE WHITING CORP., Harvey, Ill., has purchased a controlling interest in the Grindle Fuel Equipment Co., manufacturer of complete powdered coal plants for use in connection with malleable furnaces, annealing ovens, steam boilers, billet heating and various other types of furnaces. The Grindle Fuel Equipment Co. has moved its offices to Harvey, Ill., and will continue its business under the same name; the Whiting Corp. will manufacture all Grindle equipment. The following officers have been elected: President, B. H. Whiting; secretary and treasurer, T. S. Hammond; vice-president and general manager, A. J. Grindle. The members of the board of directors are as follows: J. H. Whiting, B. H. Whiting, A. J. Grindle, R. H. Bourne, N. S. Lawrence and A. H. McDougall.

JOHN T. HARRIS, of the Chicago office of the Allbright-Nell Co., transferred his activities to 829 New York Life Bldg., Kansas City, Mo., where he will act as Southwestern representative of the company.

LIPPINCOTT, MILL & Co., INC., has been granted a New York charter to deal in coal, coke, ores, scrap, iron and steel products and ferro-alloys, and to do a general importing and exporting business. The new company has offices at 17 Battery Pl., New York, and in the Hippodrome Bldg., Cleveland. G. W. Lippincott, head of Lippincott & Co., wholesale coal dealers, Hippodrome Bldg., Cleveland, is president. William H. Mills, New York, who retired 3 years ago as president of Naylor & Co. after a connection of 38 years with that interest, is vice-president and treasurer. A. L. Irwin, of Lippincott & Co., Cleveland, is vice-president. P. L. Smith, New York, for 19 years identified with Naylor & Co., resigned as assistant to the president and director of that company to become secretary of Lippincott, Mills & Co., Inc.

THE PEERLESS WIRE FENCE Co., with headquarters at Adrian, Mich., has acquired property at Memphis, Tenn., for the installation of a wire fence-manufacturing plant. Eleven weaving machines have been installed to date, and a shipment of 250 tons of wire is en route to the plant. This capacity will be doubled within the year. P. E. Underhill will have charge of the new plant, which is located at 1051 Florida Street.

ORTON & STEINBRENNER Co. of Chicago, manufacturer of locomotive cranes, clam and orange-peel buckets, has appointed the F. E. Richmond Machinery Co., 117 West Second St., Salt Lake City, Utah, as its Western agent.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN WOOD PRESERVERS ASSOCIATION will hold its annual meeting Jan. 24, 25 and 26 at the Hotel Sherman, Chicago, Ill.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

PERKIN MEDAL will be presented to William M. Burton by the Society of Chemical Industry at its meeting Jan. 13 at the Chemists' Club, New York.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Jan. 13—Society of Chemical Industry, Perkin Medal; Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Naval Influence in Abolishing Chemical Warfare

NEWS from Washington is gradually illuminating the report of the Advisory Committee to the Disarmament Conference recommending the abolition of chemical warfare. This report has always been more or less of a mystery to us because we knew that the Advisory Committee numbered among its members such men as General PERSHING, Secretary HOOVER, Senator SUTHERLAND and Governor PARKER of Louisiana. We felt that the favorable influence of General PERSHING could be counted upon, because he went on record strongly before the House Committee on Military Affairs in favor of the establishment of a chemical warfare division of the Army. The other members named we knew to have sane views on the impracticability of outlawing chemical warfare, although we felt that they might be too busy to give the subject much attetnion. Hence it was with surprise that we heard the first rumor that the Advisory Committee had resolved to recommend abolition of gas warfare. Rumors have also been afloat to the effect that the report was railroaded through the committee, and some color is lent to this statement from the fact that after the report was first submitted to Secretary HUGHES it is said to have been recalled for further consideration.

It appears now that friends of the battleship exercised considerable influence with the Advisory Committee and helped to determine its action. This is unfortunate, if true, because the Navy stands as a prejudiced party when chemical warfare is under consideration. Ever since it was demonstrated last summer that capital ships were likely to prove no match for a combination of chemical warfare and the aviation service, the Navy has shown animosity toward gas warfare. But our objection lies deeper than this. Comparatively speaking, the Navy knows little about chemistry—far less than the Army. The latter has made great strides in the application of chemistry in the solution of its problems and it appreciates chemists and their services. In these two respects the Navy has shown few signs of progress and some evidence of a reactionary spirit. Its chemists are on a per diem basis and are classified with "clerical, drafting, inspection, watchmen and messenger service."

Viewed in this light, it is hardly fair, as reported, that naval influence should be powerful enough with the Advisory Committee to influence its action. We have already expressed our feeling that the Disarmament Conference made a mistake in adopting this resolution, and we still express the hope that when the time comes for ratification of treaties the Senate may be persuaded to dissent.

It may be argued that the Advisory Committee can take refuge in the results of its survey to discover popular opinion on the questions brought before the Disarmament Conference. The statistics are interesting, indeed startling, but in our judgment they are without practical value. They are utterly discordant and irrelevant and show no constructive thought. There is evidence of voting by organizations and societies, many of which may have had predetermined partisan purposes. Thus while only 220,896 actual signatures were received, there was a vote of 1,093,535 for an association of nations. For open sessions of the Conference there were 1,056,499 votes; and we know that open sessions as popularly conceived were impracticable. Only 5,499 thought that Far Eastern questions should be considered, and yet these were of the utmost importance in their influence for war or peace within the next generation. As many as 395,104 votes favored abolition of submarines, but the Conference merely limited their use in warfare and did not abolish them. So we are not impressed with a vote of 366,795 for abolition of gas warfare. The figures merely reflect uninformed opinion on the part of a selected group.

Will the Industries Absorb Chemical Graduates?

IN HIS recent speech before the Chicago Section of the A.C.S., Dr. JOHN JOHNSON of Yale University stated that the electrical industry is the only industry in the United States well supplied with technically trained men in executive positions. While he did not enlarge upon this comparison of the electrical industry with the chemical and process industries, it may be advantageous to study the personnel conditions in each field.

About 20 years ago, when the electrical industry was in the more scientific stage of development and many questions of technology were being settled, involving need for research in physics, electrochemistry and new engineering design, men like STEINMETZ, EDISON and WHITNEY received much publicity about their accomplishments. Electricity was coming into wider use, and construction and operating men were becoming known for their work over the whole country. As a consequence there was a rush on the part of high school graduates to our universities demanding education in this field so fertile for individual progress. When they began to finish courses in electrical engineering the profession was thought to be overcrowded. It was in fact so far as opportunities for pure engineering were concerned, for the standards of design were rapidly being established.

The industrial folks, however, were not found sleeping. Taking cognizance of the situation, such manufacturers as the General Electric Co., the Westinghouse Co. and, in the public utility field, the Cities Service Co., arranged to take graduates into their testing departments where pure engineering with study of apparatus is involved. Here at the rate of hundreds per year they were

gradually educated to appreciate the many phases of the electrical business and finally tempted into production, sales and management. They were allowed to choose the branch most suited to individual temperament.

Not a few remained active in the pure engineering phase of the work, but the majority by reason of birth and home training found a natural taste for the business phases. As a result the industry has become saturated with technically trained men. The manufacturers naturally welcome the final graduation from the manufacturing side and the entry of these men into public utility service as managers and operating chiefs with customer companies. While the manufacturer has turned a deserved business advantage for himself, he has by the same policy performed a great service to the electrical industry.

The chemical industries are now in a position approximating that of the electrical industry when the education of the student for the field was undertaken. Many chemically trained men are coming through the universities each year. The chemical industries, including manufacturers of fine and heavy chemicals, coal-tar products, dyes, explosives, electrochemical products, fertilizers, alcohol, etc., must take these men and turn them into paths where they are greatly needed.

Nor may the manufacturer stop by obtaining men for his own particular work. He should turn out men for his customers, the process industries where chemical control is essential. For the makers of animal products, plant products, soap, sugar, food products, leather, paper, etc., including about twenty major fields, are the customers of the chemical manufacturer and in some cases must be educated to the consideration of technology.

No one is better suited to do this work and can profit more in the doing than the manufacturer of chemicals. The greatest good may come to American business if these graduate chemists be saved from throwing over their profession in disgust.

Coal and Coke In 1921

THE first weekly report on coal production from the United States Geological Survey for this calendar year is of particular interest because it gives preliminary estimates of the production of bituminous coal, anthracite coal and beehive coke for the year 1921. These figures for coal indicate just what one would expect—namely, that the production of bituminous coal has been very low, in fact distinctly lower than any previous year since 1911. This is a natural result of the depressed business conditions of the period, and it would have been possible only under such conditions. As would be expected, the anthracite production has been about the same as for the decade past, since this coal represents principally domestic fuel demands and is largely unaffected by business conditions of the country.

The total coke production of the country is estimated as approximately 26,000,000 tons—in other words, much less than during the previous ten-year period, but a large proportion of the decrease from the years immediately preceding was caused by the decrease in beehive and the relatively small part of the decrease was caused by the diminution in byproduct coke output, large though this latter decrease was.

The most encouraging point in the year's summary is the fact that it was primarily the output of beehive coke which was so much lower than for many years past. In fact it decreased by 74 per cent from the output of 1920, and was only about one-seventh of that of 1916, during which year the beehive coke industry reached "the high point of prosperity." To find a year when production was as low as during 1921 one must go back to 1885, when practically the same quantity of beehive coke was produced—namely, a trifle over 5,000,000 tons.

It is a splendid condition of industry that permits the fluctuation thus to occur almost altogether in the wasteful and inefficient branch of industry and permits the more efficient portion to continue to function at higher rates despite the decrease in total business.

Speaking Of Thrift

THIS week we celebrate the anniversary of BENJAMIN FRANKLIN'S birth, and we are all urged to give consideration to the cultivation of habits of thrift. Why is it that when anybody tells us to save our money we resent it. Of course, we want everybody to understand that we know how to manage our own affairs, whether we do or not, but we are especially sensitive to advice about saving. Indeed, the more we need to save the less we like to hear about it. We like to think, and indeed the less intelligent of our number continually do cry, that to save is a virtue that the very stupidest may practice. Then, when our wits have left us entirely, we like to chuckle over the idea that rules for dullards do not apply to us.

We venture the belief that the fault is in the capsule and not in the medicine. We should save; it is a good thing to do it, and it is bad for us as well as for the general welfare to waste our substance; to throw away uselessly what we have earned. It should not be an offense to urge us to save. It does not offend to urge us to read philosophy or history, for instance. If someone says of SUMNER'S "Folkways," "It is hard reading, but meaty; you will enjoy it," it flatters our vanity; it indicates that we can understand what others cannot. Then why not appeal to vanity or at least to self-respect in urging people to save?

Consider the Hearst newspapers, edited for the lowest orders of intellect that can read at all. And yet the billboards declare that, for instance, the New York *American* is "A Newspaper for Men Who Think." A glance at the physiognomies of the readers of the Hearst newspapers in street cars discourages belief in the statement—but not among the readers. They think they think. Everyone thinks he thinks.

Now the facts about saving do not coincide with the usual advice. The ability to save is not as common as dirt. It takes intelligence to save, and to be able to do so is a gift. Whoever can practice the art may be stupid in regard to descriptive geometry or physical chemistry or the music of such modern composers as MAX REGER, or SCHOENBERG, but he is not feeble minded in regard to saving. We are all feeble minded in one respect or another, but the all-round feeble-minded person cannot save. And yet so much emphasis has been laid on the thrifty dunderhead that the impression has gained ground that only the imbecile are provident.

The idea is totally wrong. The half-wit may hoard a few dollars from some remaining instinct that he cannot explain, but in ninety-nine cases out of a hundred it is soon wasted. It takes long-range vision to save. It does not call for self-denial or Pollyanna goodness. It calls for a look ahead long enough to see between a

present fancy and a greater purpose. It calls for ability and character and a certain sporty quality to stick to a purpose. If we want to refer to persons who work with their hands or who do not wear expensive clothes as "the plain people," why not discriminate between those who can save and those who cannot? They are different. The savers are better and more able in this respect, and they deserve credit for it. Why not give it to them? They will respond, and many of them will even read "Folkways." Then, when they have read that book, they will not read yellow newspapers that strive to make their readers angry in order to keep their attention. The savers will prefer constructive literature that induces human progress.

The Distribution Of Steel Consumption

A STUDY of the greatly varying rate at which steel has been produced in the past 13 or 14 months and of the accumulation and liquidation of stocks of steel and of manufactured goods made from steel indicates that there has probably been but slight variation in the rate of actual ultimate consumption of steel since the collapse of the high-pressure demand in the steel market late in 1920. Such a conclusion is reassuring both to the steel-making industry and to business generally. When, last July, the production of steel ingots dropped to a rate just one-fourth the average rate in the first 9 months of 1920, the steel makers were more or less alarmed. Before the war there had been a tradition, supported by actual experience, that the "hard times" or irreducible minimum of steel demand was fairly definite, commonly designated as 50 per cent of capacity.

Without going into details, it may be stated that without any strain of the imagination it can be conceived that the ultimate consumption of steel and steel products has been fairly uniform since late in 1920. The steel consumed is represented by a steel ingot production at the rate of 22,000,000 tons a year, which is the rate at which steel was produced during the last 3 months of 1921. The theory before the war was that it required a certain amount of steel simply to keep the country going, while whenever the country was expanding its facilities, a great deal more steel would be required, for almost any kind of industrial or commercial expansion involves putting steel into employment, chiefly in what is called "investment construction."

Unfortunately it is impossible, except by an amount of work that nobody seems willing to undertake, to make an exact analysis, either for a year or a period of years, of where the steel we make actually goes for the purpose of performing its ultimate service, but rough approximations are by no means difficult. Certain lines of consumption are seen to be relatively stable. Judged by present prospects and by the actual record of the past half dozen years, the largest steady customer of the steel industry is the oil trade. For maintaining the production of petroleum about a million gross tons annually of steel tubular goods is required, with considerable quantities of other steel, particularly of plates for storage tanks. Apparently insignificant from the tonnage standpoint, tin plate can be counted upon to involve about one and a half million gross tons. There have been two "off" years recently in tin plate—1919 on account of stocks of about 8,000,000 boxes on Nov. 1; 1918 a safeguard in connection with the war, and 1921 on account of stocks of prepared goods which the public would not buy at the prices originally asked. The automobile industry is a steadier consumer of steel than is commonly supposed. It is not generally realized that beginning with 1916 the production of passenger automobiles other than Fords has not varied very greatly and has not materially increased. The production of Fords has increased sharply. The consumption of rolled steel in automobile building is, however, scarcely 750,000 gross tons a year, so this is a minor item compared with tin plate or the steel used by the petroleum industry.

The cases mentioned above are of regular consumption, merely that the country may keep going. In many lines both upkeep and expansion are involved. In railroading, for instance, it requires about 1,500,000 tons of rails a year for replacements, while additional rails are required when new track is laid.

The year 1921 furnished a crucial test. There was very little steel consumed that did not absolutely have to be consumed, and the steel industry is now furnished with a measure of the amount of backlog business it can count on with practical certainty, this to be added to by such expansion and progress as financial and commercial conditions may warrant from time to time.

Omnia Mutantur Nos et Mutamur in Illis

LATELY we saw a note made by Dr. CHARLES BASKERVILLE in his diary at the Pittsburgh meeting of the American Chemical Society in 1902. Dr. IRA REMSEN was in the chair as president, and Dr. THEODORE W. RICHARDS had presented a paper on "The Compressibility of the Atom." As soon as he sat down "a very well-dressed chap arose and said, 'I have a machine here with which you may see the millions of atoms in rapid motion.' REMSEN promptly declared, 'There being no discussion of the paper, I shall call on —— [the author of the next paper on the program] for his communication.' The individual referred to slapped the top down, picked up his books, jammed his hat upon his head, and marched off in a huff. REMSEN then remarked: 'I must apologize to the Society for my abrupt method of shutting off discussion of Professor RICHARDS' excellent paper, but subsequent events apparently have verified my diagnosis.' "

In the margin was a note made by the diarist many years afterward: "Could this have been an ultra-microscope, and was R's mind closed to such a conception?" Maybe so; maybe so. But were not the minds of most of us closed to such a conception—only 19 years ago? We should also like to know who the "well-dressed chap" was. We can think of one who might have been he who thought he had a machine in which he could see atoms—and may really have had it—but the fact that the person was well dressed rules out our candidate.

Without question we are living in darkness even today. What is, then, the specific feature of our ignorance that hides the light from us? Is it because we know so little of isotopes? Is it because we lack the shepherd's art of herding electrons? Or because our sense of positive electric charges is so hazy? Will IRVING LANGMUIR rob us of our benzene ring?

Without a doubt both you and I
Will be regarded, by and by,
As very odd and very queer
By all the people living here.

Old and archaic we shall be;
They'll say we lived so curiously.
They'll wonder at our negligence
And why we hadn't better sense.

Perkin Medal Is Presented to William M. Burton

The Discoverer of the Burton Process of Cracking Petroleum Distillates Receives the Fifteenth Award of the Society of Chemical Industry—Addresses by Officers and Prominent Members of the Society—Presentation by C. F. Chandler and Acceptance Address of William M. Burton

PRESENTATION of the fifteenth Perkin Medal to be awarded by the American Section of the Society of Chemical Industry for meritorious accomplishments in applied chemistry took place in Rumford Hall, New York City, on Friday, Jan. 13. The medalist was William M. Burton, president of the Standard Oil Co. of Indiana and famous for the discovery and large-scale development of the Burton process of cracking petroleum distillates. Seldom, if ever, in the history of the Society has the Perkin Medal been awarded under such auspicious circumstances nor to an investigator whose work has so profoundly affected one of the country's great industries.

In the course of his introductory remarks the chairman, Sumner R. Church, called attention to the distinguished presence of all of the four past presidents of the American section. With considerable regret, however, he announced that Dr. R. F. Ruttan, present head of the Society of Chemical Industry, had been prevented from attending the presentation meeting because of a severe physical disability.

Reminiscences by Dr. Remsen

The first speaker to be introduced was Prof. Ira Remsen, often called the "father of chemistry in America." In his characteristic manner he gave a most interesting and intimate insight into the life and work of Dr. Burton. He recounted many personal reminiscences of his early association with his former student who was then continuing his graduate studies in the laboratories of Johns Hopkins. The investigations at that time were into the realms of pure science and, with his usual good-natured humor, Dr. Remsen chided the medalist for deserting the rôle of the scientist and entering into the executive side of industry.

The formal addresses of the other speakers are presented, either in full or in abstracted form, in the following pages.

The Personal Side of Dr. Burton

By Charles H. Herty

The charm of biography persists always. The results of a successful man's work are set forth in the public record, whether it be in the form of scientific publications, of official status, of some great engineering feat, of the size of his income tax, or what not. Back of the life accomplishment, however, is the personality of a human being who, following the bent of his own genius, has triumphed over the difficulties which beset us all.

What manner of man did it? That is the question which kindles a different kind of interest from that due to a knowledge of what the accomplishment is. For out of such studies of many types of men we gain here and there suggestions, self-applicable, which help us over our own rough spots and give us hope.

In the case of Dr. Burton, or "'Billy," as he was called by us in student days at Johns Hopkins University, there is added another to the long list of successful men who were born in the country and passed their early days entirely ignorant of cement sidewalks. What a pity we couldn't all have persuaded our parents to move out to the country before we were born. At any rate, it was Billy's good luck to enter the world under such favoring circumstances in the year 1865. In 1886 he was graduated from Western Reserve University, receiving the A.B. degree. The next 3 years were spent at Johns Hopkins University, from which institution in 1889 he received the Ph.D. degree.

A Normal Individual

It is peculiarly fitting that the Perkin Medal should be awarded to him in this the first year of President Harding's administration, for right well does he represent the return to normalcy, all of his friends to whom I have written emphasizing the fact that from boyhood to the present time he has always been a normal individual. He has cultivated no particular hobby, considered by many to be essential to distinction, but has carried through life a love of experiment and an ardent zest for the lathe and mechanical tools. It is easy to understand, therefore, that in the environment in which he has worked he not only succeeded in cracking oil but carried the work on to a successful large-scale application.

He plays no outdoor games, not even golf. This sounds abnormal, but to offset it he recently obtained keenest satisfaction in installing in his home under his personal direction a radiator system at one-fifth the estimate furnished by a contractor, and who wouldn't rejoice at getting the best of a plumber? I insist he is normal.

The Significance of His Success

Steadily he has been advanced in that company with which he began work after completing his university training, until today he occupies the presidency. Throughout this advancement he has remained the same sincere, sympathetic, level-headed man to whom his friends and associates come with their problems for his sound advice.

That he has worthily won this great honor from his associates in business all agree, that throughout it all he has preserved his unaffected selflessness all will rejoice; but there is another aspect of his success which deserves not only record here but wide heralding at this stage in the development of American chemical industries. The industry with which he is connected is one of our early and now thoroughly stabilized industries, and it is peculiarly worthy of note that the Standard Oil Company of Indiana has chosen for its chief executive the chemist. Not all chemists are qualified to be executives, but certainly our chemical industries will be placed on a much sounder basis when the chemist of proper qualifications is given opportunity to share in the determination of corporate policies. Billy Burton's record may yet prove the harbinger of a new day.

The Chemist in Industry

Dr. Burton's monumental work in the oil industry was fittingly reviewed by one of his associates, Russell Wiles, patent adviser of the Standard Oil Company of Indiana, who chose for the subject of his address "The Chemist in Industry." It is only within the last few years, he declared, that the chemist has contributed his proper share to industrial progress. "Much has been done in chemistry as a pure science, but it is within comparatively recent years that the chemist has emerged from his laboratory and that industry, as a whole, has felt the need of close co-operation with him. Where 10 years ago big practical applications of chemistry were rare or confined to a few specialized industries, today there is scarcely an industry which has not been more or less affected by the progress of chemical science. Chemical inventions, at least as exemplified in my own practice, are at least ten times as numerous as they were a decade ago.

"The work of Dr. Burton, which is being so fittingly recognized, may well be regarded as rather an early example of the great things the chemist is to accomplish in the future than as an achievement which is to be unique in history. Bringing a thoroughly scientific point of view and applying to his problems the methods of pure science, with his great natural ability and indefatigable industry, it was entirely unavoidable that Dr. Burton should profoundly affect the petroleum industry in one way if not in another. No man has ever had a more promising field—an enormous industry dealing with problems which ought to be handled in an essentially chemical manner and having no chemists at all. Dr. Burton would be the first to recognize his splendid opportunity, and it is characteristic of him that his opportunity never was neglected.

Production on a Scientific Basis

"But Dr. Burton alone never could have accomplished what has been done by the Standard Oil Co. of Indiana. There has been much discussion in big corporations as to the best method of correlating the scientific force with the manufacturing force. All sorts of experiments have been attempted and all sorts of systems have been devised. The system worked out by the Standard Oil Co. of Indiana, largely at the instigation of Dr. Burton and of recent years under his guidance, is unique and amazingly successful. None but a scientifically trained man would have dreamed of such a system and the operations of the Indiana company are the best demonstration of the industrial value of scientific training.

"The system of this company is founded on the premise that a scientifically trained man is a good man for any job; the scientific staff does not co-operate with the manufacturing staff—it has become the manufacturing staff. The practice, so far as concerns chemists, has been to take on trained men for the laboratory force precisely as in many other plants. After brief association with the laboratory, during which the newcomer can become familiar with the peculiar problems of the works and particularly of some special department to whose problems he is assigned, he leaves the laboratory and goes into the works in some subordinate capacity. It then becomes his prime duty to test, on a practical scale, whatever improvements may fall within the sphere of his department. Having once become established in the works, it has been found that almost without exception the technical men become excellent executives and their promotion is rapid.

"The result is that the manufacturing department of the Standard Oil Co. not only maintains an excellent research department, but that the whole manufacturing organization from top to bottom is largely dominated and controlled by men of scientific training. The Standard Oil Co. of Indiana is unique in this regard, and the tremendous success of its manufacturing department must be very largely attributed to the superb organization which Dr. Burton conceived and has built."

The Burton Process

After showing how thoroughly this system has been applied in the Whiting refinery, which is the largest plant of the company, Mr. Wiles turned his attention to the industrial significance of the Burton process.

"No industry was ever so profoundly modified by any process as the oil business has been modified by this process. How profoundly the Burton process has affected the refining practice in plants where it is in full operation can never be thoroughly comprehended by one outside of the industry. There are, however, some points which might be overlooked which are illustrative.

"The Burton process has more than doubled the yield of gasoline from a given quantity of crude run. Practically, this means that a given quantity of crude oil supplies twice as many engines with fuel. But these engines have to be lubricated, the cars they propel have to be provided with grease, and the very road surfaces upon which they run have to be provided with asphalt. The increased supply of gasoline has enormously increased the demand for these other products, and, at the same time, the normal increase in demand for other petroleum products, such as wax, petroleum jelly, etc., has been greatly augmented, as might be expected with the increase in population.

"The problem of finding the increased supplies of all these commodities, when more than twice as much of the crude oil run is going into gasoline, has been extremely serious. Indeed, at times, some oil refineries have been essentially on a lubricant basis—i.e., the amount of crude run was determined primarily by the lubricants demand instead of the gasoline demand, but the ingenuity of the scientific staff has proved itself entirely equal to the problem. Running methods throughout the plants have become modified in one way and another to produce all the needed products in quantities so balanced as to meet the market demands, but the practical working out of the Burton process by no means has consisted in setting up the Burton stills and running them as a side line or excrescence of the refinery. The entire operation of the refinery has had to be readjusted fundamentally to co-operate with the pressure still plant.

"And it may be added that the profound shift in the ratio in which products are being produced and the practical withdrawal by the Standard Oil Co. of Indiana of gas and fuel oil from the market has very profoundly modified marketing methods. The full extent to which the changes in marketing methods, largely caused by the existence of the Burton process, may affect this and other industries in the future is problematical. The new problem was met satisfactorily but in a manner which may have far-reaching future consequences."

In concluding his address, Mr. Wiles paid tribute to his associate in the following words: "In extending to William M. Burton this highest honor in your power, you honor one who has brought honor and credit to your profession, a scientist of scholarly ideals and high at-

tainments, an organizer of broad vision and confident faith in the future, an efficient and successful executive and, perhaps greatest of all, a leader of men. Dr. Burton asks nothing of his men which he is not capable of doing himself. His greatest tribute, greater far than any award for scientific attainments, is the affectionate regard of those with whom he has worked for so many years and who know him best. Our greatest rewards are not degrees, or diplomas, medals or decorations, but the esteem and affection of our associates. These Dr. Burton has long had in abundant measure.

"But in honoring him you celebrate a great achievement of your own great profession. May this be only one of a host of like achievements which you have reason to recognize. May these awards, from year to year, mark equally great gifts to human knowledge and human comfort. The day of the chemist is here. You hold the future of industry."

Presentation Address

BY C. F. CHANDLER

It is my privilege and very pleasant duty, as senior past-president of the Society of Chemical Industry residing in this country, to present to William Meriam Burton, A.B. and Ph.D., this fifteenth impression of the Perkin Medal, in recognition of his most original and valuable work in applied chemistry.

Dr. Burton was born at Cleveland, Ohio, on Nov. 17, 1865. He was graduated at the Western Reserve University in 1886 with the degree of A.B. Subsequently he attended the Johns Hopkins University, taking the major course in chemistry under Prof. Ira Remsen, receiving the degree of Ph.D. in 1889. His papers published at this time in the *American Chemical Journal* attracted favorable attention in scientific circles.

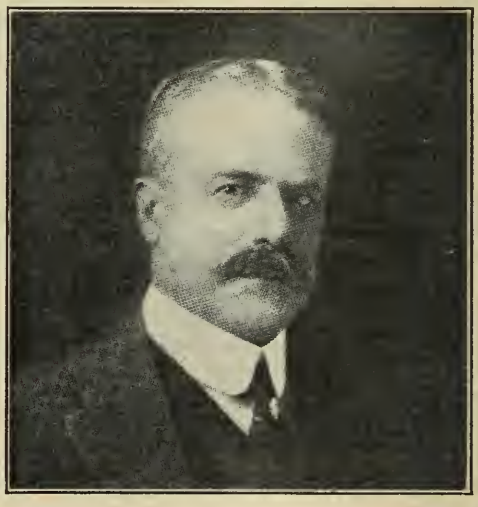
Soon after graduating he was engaged as chemist, in 1889, by the Standard Oil Co. at Cleveland, Ohio, to assist in a process for refining the sulphur-bearing petroleum from the neighborhood of Lima, Ohio. In 1890 he was transferred to the Standard Oil Co. of Indiana, where he served as chemist. In 1892 he was appointed assistant superintendent of the works, serving in this capacity until 1895, when he was made general superintendent. In 1911 he was elected director, in 1915 vice-president, and in 1918 president, which latter position he still holds.

My acquaintance with Dr. Burton began in November, 1895. At that time there was a rumor in Germany that the Standard Oil Co. reserved the pure Pennsylvania oil for the American market and sent the foul-smelling, sulphur-bearing oil from Ohio, Illinois and Indiana to Germany. It was further rumored that the German Government was contemplating forbidding the importation of this oil.

It was quite true that this Ohio oil contained from ¾ to 1 per cent of sulphur, and that when it was fractioned in the usual way, the fractions all carried portions of this sulphur and were offensive and unsuitable for the customary purposes. This was also true of the Canadian petroleum. But Herman Frash began the search for practical methods of removing this sulphur in 1885, at his Empire Company refinery at London, Ont., applying for his first patent in 1887, and by the end of 1894 had applied for twenty patents in this connection. His oxide of copper treatment applied to the usual fractions was a complete success and came promptly into use. So that the Ohio oil was in every way fully equal in purity and value to the Pennsylvania oil.

Fearing that the German Government might adopt some adverse legislation which it might be difficult to get repealed, the Standard Oil Co. requested me to go to Berlin and convince the government that there was no objection whatever to Ohio oil. In order to be thoroughly informed, I visited and carefully inspected several of the refineries of the company—namely, Olean, Lima and Philadelphia. I found Dr. Burton in charge of the Lima works, and spent a day with him. He interested me so much that I proposed that he should go with me to Berlin, to confer with the government officers.

Late in November we sailed for England and made our way to Bremen, where we consulted with the German representatives of the Standard Oil Co. We then went to Berlin and consulted with representatives of the company there. Our interview with Count Posidowski, the Imperial Minister of the Interior, was entirely satisfactory. He willingly accepted the evidence we presented and all danger of adverse legislation disappeared. For the purpose of strengthening our position we then visited the Imperial Health Department, and the two petroleum experts, Professor Engler in



WILLIAM MERIAM BURTON

Carlsruhe and Professor Louge in Zurich. We had no difficulty in satisfying all these authorities that Ohio oil was in no way inferior to Pennsylvania oil.

Thus I had the pleasure of associating with Dr. Burton on the most intimate terms for nearly 2 months and we became the best of friends. Ever since he became connected with the Standard Oil Co. in 1889 he has devoted his attention to the improvement of methods and means for converting the crude oil into the most valuable products, in the most economical manner, but his methods have rarely appeared in print.

His Great Invention

Dr. Burton's great invention, which ranks with the manufacture of oil from coal, the boring into the earth for oil by Colonel Drake, the elimination of sulphur from the Canadian and Ohio oils by Frash, was his process for distilling the heavy, high-boiling fuel and gas oil fraction and lubricating oils under high pressure, at a high temperature, in order to convert them into light, low-boiling gasoline.

In the earlier years the production of light oils, gasoline, naphtha, etc., in the fractioning of crude petro-

leum, exceeded the demand. Fifty years ago the wholesale price of refined burning oil was 25c. per gal., while the light oil, under the name of naphtha, was offered at 5c. a gal. Unscrupulous retailers bought both, and mixing them, facilitated "kerosene accidents." The last year before this condition of the oil trade was made public through the New York City Board of Health, there were fifty-two deaths, chiefly of women and children, in New York City caused by kerosene accidents. But with the introduction of the internal combustion engine and the appearance of automobiles, motor cars, trucks, etc., the demand for gasoline has far outstripped the supply.

Dr. Burton promptly attacked this problem of increasing the supply by converting the heavy, high-boiling oils into gasoline, by distilling them under great pressure at a very high temperature. It really seemed an impossible problem on account of the dangers of explosion. But Dr. Burton triumphed, and at the present time very large quantities of gasoline are supplied by this process, and the quantity may be largely increased as the process is more extensively adopted.

I have not gone into details with regard to the process, because I am to be followed by the inventor himself. Incidentally I may add that a valuable variety of asphalt is produced as a byproduct from the cracking of the distillates of the crude petroleum, used in Burton's process of cracking into gasoline.

Dr. Burton received the Willard Gibbs Medal,[1] May 17, 1918, at the meeting of the Chicago Section of the American Chemical Society, in recognition of his distinguished work in petroleum chemistry.

The following articles were published by Dr. Burton, in the *American Chemical Journal,* vol. 11, 1889:

"On the Crystal Form of Metallic Zinc," by George H. Williams and William M. Burton, page 219.

"On the Action of Dilute Acids on Benzoic Sulphinide and the Analysis of Commercial Saccharin," by Ira Remsen and William M. Burton, page 403.

"A Rapid Method for the Estimation of Sulphur in Organic Compounds," by William M. Burton, page 472.

In the *American Chemical Journal,* vol. 12, 1890, were published:

"A Method for the Detection and Estimation of Petroleum in Oil of Turpentine, by William M. Burton, page 102.

"The Atomic Weight of Magnesium, as Determined by the Composition of Its Oxide," by William M. Burton and L. D. Vorce, page 219.

U. S. PATENTS ISSUED TO DR. BURTON

Date of Application	Date of Issue	Number	Title
1904, Aug. 12	1904, Oct. 11	772,129	Process of making hydroxy stearic acid
1912, July 3	1913, Jan. 7	1,049,667	Manufacture of gasoline
1912, Sept. 23	1913, Mar. 11	1,055,707	Process of producing asphalt

* Humphreys and Burton.

Conferring the Medal

William Meriam Burton, Bachelor of Arts and Doctor of Philosophy: It gives me the greatest pleasure, as the representative of the Affiliated Chemical and Electrochemical Societies of America, to place in your hands this beautiful Perkin Medal, as a token of the appreciation and affection of your fellow chemists.

[1] See Met. & Chem. Eng., vol. 18, No. 12, p. 647, June 15, 1918.

Address of Acceptance

By William M. Burton

The notification from your secretary, Dr. Rogers, that I had been appointed as a recipient of the Perkin Medal came to me as a most unexpected but happy surprise. The awarding of the Willard Gibbs Medal to me in 1918 would seem to be sufficient recognition, on the part of American chemists, of the industrial work that has been done under my direction; and now comes this additional honor and distinction. I appreciate in the highest degree the compliment this medal conveys, and I hasten to express my most sincere thanks to the members of the awarding committee and to the societies they represent.

The work done under my direction which has perhaps attracted the most attention was carried on principally in the laboratory and refinery of the Standard Oil Co. at Whiting, Ind., a suburb of Chicago, and consisted in devising ways and means for the practical conversion of high-boiling fractions of petroleum into low-boiling fractions in such a way as to insure substantial yields of suitable products with a minimum loss and at a reasonable expense.

The Problem of Motor Fuel

The problem became imperative with the advent of the internal combustion engine about 15 years ago. The most commonly known example of such an engine is, of course, the automobile motor, which, as constructed today, requires a fuel that evaporates at comparatively low temperature, has a high heat value expressed in British thermal units, burns without leaving objectionable residues, does not possess an objectionable odor, is low priced and can be produced in large quantities. Benzene, toluene and alcohol are fairly well suited for the purpose, but their cost and their small volume of production render them largely unavailable.

The low-boiling fractions of petroleum naturally come into use for this purpose, and up to about 1910 the supply of this fuel was sufficient to meet the demand. In fact, the automobile provided an outlet for the sale of these products, which to some extent had been a drug on the market in the oil world. The older refiners in the country will remember when these so-called naphtha products were thrown away and permitted to run down the streams adjacent to the refineries, thereby causing a willful waste and a fire menace to the neighborhood.

Prior to 1910 the average yield of naphtha or gasoline products from crude oil in the United States was about 11 per cent. This yield represented only the amount of such products (of the quality desired at that time) normally present in the crude petroleum and capable of being separated by ordinary methods of distillation at atmospheric pressure. Furthermore, this small yield was sufficient to furnish all that was needed for gasoline stoves and other industrial purposes prior to the use of the internal combustion engine for transportation purposes.

When the automobile came into general use, however, it was perfectly clear that the normal yield of naphtha products suitable for fuel in self-propelled vehicles would not be nearly enough. At that time our refineries were selling about 40 per cent of the products of crude oil for use as fuel and for gas-making purposes in lieu of coal. The remaining 60 per cent represented the normal yield of naphtha and gasoline, illuminating and lubricating oils.

The above-mentioned 40 per cent fuel and gas oil comprised fractions boiling between 225 and 375 deg. C. These oils could, if necessary, be withdrawn from the market, and our problem was to convert them so far as possible into fractions boiling between 40 and 200 deg. C., the product to be equal in quality to normal naphtha products and the yield and operating expense to be commercially feasible.

Our first experiments were directed toward making a suitable product by superheating the high-boiling vapors as such, but without pressure, somewhat along the practice observed in making pintsch gas. We soon found, however, that this so-called "cracking" in the vapor phase required a temperature so high that the aliphatic hydrocarbons contained in the petroleum were largely converted into cyclic and aromatic bodies and fixed gases—unsuited for our purpose. The yield was poor and the quality most undesirable. Obviously our problem included the proposition of reducing the molecular weight without changing the general structure.

We next tried the use of various reagents and catalyzers, such as aluminum chloride and ferric oxide. Anhydrous aluminum chloride, indeed, produced some rather remarkable results. The yield and quality of naphtha products were fairly satisfactory, but there was a substantial loss of oil in the operations and the first cost of the anhydrous aluminum chloride, as well as the difficulty in recovering it from the residues, rendered this plan unattractive.

Nearly 30 years ago Sir Boverton Redwood and Professor Dewar in England had patented a pressure-distilling process for the purpose of increasing the yield of kerosene oil from the residues of Russian crude petroleum, but it never was applied industrially. It had been known, therefore, for some years that distilling petroleum under pressure served to break down the high-boiling fractions into low-boiling fractions but, as far as we could learn, no one had ever done it on a large scale and, in fact, such a proposition could not commend itself to a practical refiner because of the obvious dangers from explosions and fires that would be present in handling large stills under such conditions.

Experiments With 100-Gal. Still

But having tried everything else that suggested itself, we attacked the problem of distilling petroleum in considerable quantities (8,000 to 12,000 gal.) under pressure of about five atmospheres. The first still we built was of a welded design and was planned to handle 100 gal. of the high-boiling fractions. Obviously, the raw material first to be tried consisted of the so-called fuel oil, or reduced crude, meaning the residue of crude oil after the more valuable products had been removed. We soon found that we could not work profitably with this product; when distilled with or without pressure it produced quantities of coke that deposited on the bottom of the still and caused a red hot bottom that would not stand any rise in pressure. The next proposition comprised the use of high-boiling distillates from the crude —viz., oils boiling from 225 deg. C. upward. By using these oils as raw materials we obtained our first encouraging results. We distilled these distillates at a pressure of about five atmospheres and were thereby able to hold down the temperature to a moderate figure, the cracking being done in the so-called liquid phase. By doing the work in this way we found to our intense gratification that the low-boiling fractions produced belonged mostly to the aliphatic or paraffine series, which were easily deodorized and finished into products suitable for sale. Further, the yield of salable liquid was good and the production of fixed gases and coke small.

The First Commercial Pressure Still

Experimentally, therefore, our work was successful. But the big problem remained to be solved. Could we build large equipment that would, in a practical way, obtain the desired results and at the same time be durable and reasonably free from the fire hazard that always attends operations in an oil refinery? Some of our practical men said we could, but more of them said we couldn't. In this case, however, the majority was overruled and we immediately prepared plans and specifications for a still 8 ft. in diameter and 20 ft. long built of ½-in. mild steel plates, and holding a charge of 6,000 gal. of raw material. It had a safety factor of 5, the working pressure to be 100 lb., and the bursting pressure 500 lb.

The still was built and charged, with many misgivings on the part of the doubters, but with boldness and confidence exhibited by the rest of us. So soon as we had the still hot and pressure began to develop, we encountered our first difficulty. The still was built in a workmanlike manner and would have made a good steam boiler, but we found rivets and seams leaked badly under oil pressure where they would not under steam pressure. It was difficult to induce boilermakers to calk the leaks while the still was hot and under pressure, but we found men bold enough to do it and the first run was sufficiently encouraging to induce us to proceed further. But the leaks persisted until Nature came to our aid and the minute portions of oil in the leaks gradually carbonized and they closed without our aid.

The experiments with the large still proved our results with the small one—viz., the yield of suitable gasoline fractions was good; the loss was trifling; the cost was reasonable, and the fire hazard under close caution and supervision was not excessive. In addition, we were astonished to find that the residue remaining in the still contained substantial quantities of asphaltine actually created (from a distillate containing none of it) by distillation under pressure.

Minor Difficulties to Be Overcome

We learned early in the work that operating at moderate pressure required a substantial dephlegmating system that would return to the still the fractions boiling too high for our purpose, and permit the others to pass on. A suitable safety valve that would operate properly with oil vapors at high temperature had to be devised. It would require much more time than I have at my disposal this evening to give a full account of the many difficulties that arose. We had solved the big points, but there were many smaller ones. For successful results we must operate with the oil at temperatures from 370 to 400 deg. C. in the still. At 450 deg. C. steel begins to lose its tensile strength and its capacity to withstand pressure. It is clear, therefore, that with this narrow margin great caution must be exercised to prevent overheating. The human element enters here, as it does in every feature of pressure-still operation, but we operated over 8 years with hundreds of these stills in daily use, and manufactured millions of barrels of gasoline by this method before we had a fatal accident.

After making a number of runs with our 8 x 20 still, and in view of the fact that the demand for gasoline

was increasing at a rapid rate, we asked for an appropriation of $1,000,000 to build sixty pressure stills 8 ft. in diameter and 30 ft. long, each charging 8,000 gal. of raw material. It required considerable argument to convince any of our directors that such a revolutionary proposition could possibly be successful, but finally they voted in favor of it, and we went ahead.

The Problems of Today

From the humble beginning of the 100-gal. still in our experimental laboratory, the Standard Oil Co. of Indiana has in operation today over 800 pressure stills having a gross charging capacity of 8,000,000 gal., and licensees under our patents are operating as many more, giving a daily production of 2,000,000 gal. of gasoline out of the total of about 12,500,000 gal. produced daily in the United States and Canada.

This amount of gasoline makes possible the use of two millions of motor vehicles more than could otherwise have been supplied from a given consumption of crude petroleum, and as a corollary of that proposition and assuming 20 per cent of gasoline as a normal average yield from crude oil, the pressure-still process is conserving for future consumption an amount of crude oil equal to nearly one hundred million barrels per year.

The consumption of gasoline by internal combustion engines during the past decade has increased at a terrific rate. In 1910 the United States consumed approximately 700 million gallons, while for 1920 the Bureau of Mines statistics show a total gasoline production of 4 billion 600 million gallons, of which 850 million were made from natural gas, something over 3 billion gallons made by straight crude oil distillation and 750 million gallons made by the cracking process. Further, statistics show that while the increase in crude oil production during the past decade has been 142 per cent, the increase in gasoline production has been over 700 per cent, and although some of this gasoline has been exported, the larger portion has been consumed by the ever-increasing number of automotive vehicles in this country.

The increase in production of crude oil has not been commensurate with the increased demand for its products, and the pressure-still process filled at least part of the gap. Naturally, one is inclined to speculate on what the future will be regarding an adequate supply of these important commodities. One suggestion would be that some of the large amounts of oil now being used for fuel and gas-making purposes be replaced with coal and substantial portions of the oil used for making gasoline, the coal consumption, in turn, to be replaced in part by the development of hydro-electric power.

The American people are notoriously wasteful in the use of natural resources with which they are so highly endowed. It is hoped the work outlined above will be considered a slight contribution toward the curtailment of such waste.

Acknowledgment

It would be obviously unfair and unjust to close this paper without duly acknowledging the work done by my associates in successfully establishing the pressure-still process. Our patent attorneys, represented by Russell Wiles, contributed many useful and practical suggestions, and if it had not been for the invaluable assistance of R. E. Humphreys, E. M. Clark, T. S. Cooke and many others connected with the Standard Oil Co. of Indiana, satisfactory results would never have been obtained.

Tungsten in the United States

Conditions affecting the production of tungsten in the Boulder County, Col., district are outlined in a report just issued by the United States Bureau of Mines.

It was not until 1900, after the Caribou and Boulder County silver mines had been operated for 30 years, that the heavy dark mineral found as "float" and known to the miners as "heavy iron," "black iron" and "barren silver" was recognized as an ore of tungsten. There was no development of importance, however, until 1914 when the war-time demand for high-speed tool steel, of which tungsten is usually a component, became so great as to cause feverish activity among the owners of the known Boulder County deposits.[1] In the tungsten mining camps the high prices brought about a boom similar to the booms caused by important gold discoveries. The price of tungsten rose to unheard of heights, $75 a unit or more being the quotation for nearly 2 months, and at least one lot is known to have been sold for $105 a unit. Such high prices caused the large users to import tungsten ores from South America, and later China, as these foreign ores could be laid down in this country very cheaply. As a result of these importations the market broke rapidly, and during the later part of 1916, 1917 and nearly all of 1918 the price was fairly steady at about $25 a unit. The small demand, upon the signing of the armistice, together with the large importations and stocks held by dealers, forced the price down so much that early in 1919 all of the Boulder County producers were forced to suspend operations.

Besides the well-known uses of tungsten for high-speed tool steel and incandescent lamp filaments it has been used for replacing platinum and platinum-iridium alloys for contact points in spark coils, voltage regulators, telegraph instruments and other electrical devices; wrought-tungsten targets for X-ray tubes; finely divided tungsten as catalytic agent in the production of ammonia from nitrogen and hydrogen; permanent magnets made by heating and quenching a steel containing 4 to 5 per cent tungsten and 0.5 to 0.7 per cent carbon; and in gas engine parts, such as valves.

Exports of Vanadium From Peru

Consul Claude E. Guyant of Lima reports in the Jan. 2, 1922, issue of *Commerce Reports* that during the calendar year 1920 198,760 sacks of vanadium ore, aggregating in weight 10,534 metric tons, were exported from Peru, all shipped to New York, the value of the ore being 2,474,562 soles, which was equivalent to $1,237,281 (sole = $0.50)—i.e., 234.90 soles ($117.45) per ton.

In the first 6 months of 1921 there have been only four shipments of vanadium ore, aggregating 44,562 sacks with a total weight of 2,362 metric tons, valued also at $117.45 per ton, despite the fact that Peruvian exchange has been more than 20 per cent below par during the year.

The local office of the corporation that has been the principal exporter of this ore advises that the maximum vanadio-acid content of the Peruvian product during the past 2 years has been 26 per cent, the average being 20 per cent.

[1] The development of milling practice in Boulder County, the ore-dressing methods in use and the local manufacture of ferro-tungsten and tungstic oxide are described in Bulletin 187, "Treatment of the Tungsten Ores of Boulder County, Colorado," by J. P. Bonardi and J. C. Williams, which may be obtained on application to the Director of the Bureau of Mines, Washington, D. C.

What Are the Universities and Technical Schools Doing to Train Their Undergraduates in Industrial Relations?*

The Engineering School Curriculum Should Contain Courses in the Principles of Industrial Organization, Cost Finding, Wage System and the General Economics of Industry — Study of Human Relations Important—Student Should Be Prepared to Build a Better Industrial World

BY DEXTER S. KIMBALL
Dean, College of Engineering, Cornell University, Ithaca, N. Y.

THE question, "What are the universities and technical schools doing to train their undergraduates in industrial relations?" is very closely tied up with the question, "What *can* universities and technical schools do along these lines?" and a consideration of the latter question is in a measure an answer to the former. Both questions involve a consideration of the basic function of such institutions.

One of the most important developments of recent years is the popular recognition of the efficiency of engineering methods. A few years ago the word "engineering" was used almost exclusively to denote activities connected with the design, construction and operation of machinery, the construction of highways and bridges and similar undertakings. Today we hear of "Industrial Engineering," "Efficiency Engineering," "Financial Engineering," "Human Engineering," and others of similar portent. At first sight some of these terms may seem unwarranted, but they have been coined for lack of better nomenclature. They simply indicate the gradual passing of the old empirical and speculative methods of attacking the problems of industry and the steady growth of the more scientific methods that have become identified with the work of the engineer and scientist.

Existence of Engineering Type of Mind Must Be Recognized

Not less important is the recognition of the existence of the engineering type of mind just as we have long recognized the legal type of mind. Natural talents differ, one man being well suited for the study of law and another for the study of engineering or some other calling. The engineering mind is the result of a fairly definite training of an intellect fitted for such work, and the same is true of law or medicine. And it should be carefully noted that this training is fairly well defined in both quantity and content. If this were not so, it would be possible to develop lawyers on some other basis than is now employed and doctors could no doubt be trained without studying medicine. Any course of technical study, therefore, that involves a marked weakening of the fundamentals of engineering education cannot be expected to produce men with engineering minds, and this should be kept constantly in view in discussing the possibilities of the engineer in any portion of the industrial field.

Now the engineer has found an ever-increasing field of usefulness in recent years. Viewed originally as a technical adviser of industry, he has been gradually drawn over into the administrative field, from the very necessities of the case. As industry has become more technical and more complex it has been found imperative to employ technically trained men to supervise industry of many kinds. And the technically trained man, bringing his own peculiar methods to bear on problems of administration, has already made an assured place for himself as an executive. There can be little doubt that the near future will see the engineer a dominant figure in the administrative side of industry. This must necessarily be so in a civilization such as ours, which depends so largely upon engineering for its existence. As a result of these extended activities, there has grown an increasing demand from practicing engineers and employers that engineering students be given some instruction in economics and such allied studies as refer to the problems of management. And hence practically all good engineering schools in this country include in their curriculum more or less instruction along these lines.

Study of the Human Factor in Industry

But this closer contact with the administrative side of industry has brought the engineer face to face with the greatest problem of all ages—namely, the status of the human factor in industry. Whether he wills it or not, he must face this problem and make an effort to solve it. Others have tried with little success and it remains to be seen whether the engineer with his more scientific methods of attacking industrial problems will succeed in solving this most ancient of all industrial problems.

A recognition of this further extension of the engineer's activities has brought an insistent demand that the curriculum of engineering schools be still further modified to include instruction and study in human relations. The demand is logical and deserves very careful consideration on the part of those who are responsible for technical education. As yet no marked modification of this kind has been made except in a few isolated instances.

While the *character* of the modifications desirable in engineering curricula is well defined, the *degree* to which it is permissible to carry these modifications is not so obvious. Every technical school in the land is beset by urgent requests, in some cases amounting to a demand, that the course of instruction be modified to suit some peculiar industry or the opinion of some particular group of people. Financiers and bankers wish to have their particular field more fully represented. The advocates of the many forms of efficiency engineering have their own peculiar modifications, and those interested in uplift work are advocating complete courses in "human engi-

*Reprinted from the *Proceedings* of the Academy of Political Science, Kent Hall, Columbia University, New York City, vol. 9, No. 4, January, 1922, on "Constructive Experiments in Industrial Co-operation Between Employers and Employees."

neering" (which expression I detest) to replace in a large measure the courses of instruction now in use.

The tendency of the overenthusiastic teacher is to answer these many and conflicting demands by organizing highly specialized courses of instruction that will prepare the student admirably for a definite and narrow portion of the industrial field at the expense of a broad and solid foundation for his life's work. As a consequence there are now appearing in answer to these demands some narrow and highly specialized courses of instruction such as are suggested in the foregoing. We find elaborate shop organizations for teaching the details of scientific management, so called, and several varieties of special courses in administrative engineering; and some courses have already been established in human engineering, whatever that may be.

Highly Specialized Courses Demanded by the Industrial Manager Not Desirable

Now without doubt there are some places where special courses of the kinds mentioned are justifiable in the higher technical schools just as specialized trade schools are often justifiable in the lower grades of educational activity. But these special courses do not solve the general problem and there are certain grave objections to these highly specialized courses so strongly demanded by the industrial manager. It should not be forgotten that the *primary* reason why the engineer has been found useful in managerial work is his knowledge of the fundamentals of engineering design and construction and the trained mind that he brings to the consideration of problems of management and organization. That is, aside from personal qualifications that are inherent and cannot be acquired, the technical graduate is good material from which to make an executive simply because he is primarily an engineer by training.

The character of engineering fundamentals and the amount of time that should be spent upon each one is fairly well agreed upon by educators and engineers who have given this matter careful thought. And the constant pressure that has been exerted for many years upon the technical colleges by the advocates of special training of many kinds has resulted in reducing these fundamentals to a minimum. This in itself has been a beneficial influence, but it must not be extended too far. It is not claimed, of course, that the content of these fundamentals, or the methods of presenting them are all that is to be desired. There is much more work to be done along these lines than some of us may be aware of. But at the most these fundamentals can only be concentrated and made more presentable; they cannot be eliminated as some would have us do and still prepare men who will possess the engineering mind. In engineering colleges that require the equivalent of a high school training at entrance it takes about three years to teach the average student the fundamentals of engineering, leaving one year in which to give him some practical applications of these fundamentals in some particular portion of engineering practice. This year of application is not necessarily the senior year, but may be spread out over one or more of the last years of college life. This amount of academic time is also available, therefore, for special instruction in economic and humanistic studies for those who wish to pursue an administrative career.

There is of course the alternative so often and so naturally advocated of lengthening the college course to five or even six years as has been done to some extent in law and other courses. A discussion of this solution is beyond the limitations of this article. This solution has been tried in several places but so far as the writer is aware there is little reason to believe that such a lengthening of the course will become universal in the near future, and there is no reason to believe that the arguments that resulted in lengthening the course in law are fully applicable to engineering. This discussion will be confined therefore to standard four-year courses which normally send the graduate into the practical field at about twenty-three or twenty-four years of age. In general, the writer believes that this is about as late in life as a young man should begin actual service in the industrial field.

Educational Content of a Four-Year Course

The particular problem under discussion reduces itself, therefore, to the selection of an educational content that can be incorporated into the ordinary four-year course of instruction that will give all students in the college some instruction in the fundamental principles of organization and management, some instruction in basic economic theory and as much instruction as possible in subjects dealing with human relations in industry. This content, so far as industrial organization and economic theory are concerned, is not difficult to find. Thus all engineers should receive instruction in the elementary principles of industrial organization, cost finding, etc., wage system, time and motion study and the general economics of industry. If possible, these subjects should be given before the senior year so that in the senior year the student who so desires may specialize as far along the lines of industrial organization as other students can in such lines of study as gas-engine and steam-engine design, electrical engineering, etc. Space forbids a more detailed statement of such a plan, but actual experience has already shown that such a course will give the student a sound engineering foundation and a good grasp on the fundamentals of economics and industrial organization and management. It will not develop specialists in this or any other line of work nor will it necessarily develop the peculiar personal qualities so often demanded by industrial managers who have peculiar managerial problems to solve.

Content of a Course in Human Relations in Industry Difficult to Define

The educational content of a course in human relations in industry is not so easy to define despite the very large amount of literature that has appeared on this subject. Of course a considerable discussion of human relations in industry is necessarily involved in any discussion of industrial management. But the entire subject of human relations is controversial, to say the least, at present, and the teacher can find little in the industrial field itself that will aid him in drawing accurate conclusions. Certainly the average industrial manager can throw little light upon the most important matter if the results one sees in the industrial field are any indication. Of course there is a considerable literature of the "uplift" kind and there have been many experiments along the line of welfare work, so called, which, because of their failures or successes, indicate that certain efforts may be desirable or undesirable. But a sound philosophy of what human relations in industry should be has not as yet been formulated—at least none that goes beyond a general advocacy of the Golden Rule. Perhaps all that the teacher can do is to call the attention of the student

to this field and direct his thoughts to this, the greatest of all problems. This in itself is something, as it should stimulate the thoughts of these future industrial managers to think of these matters at an early age and long before the age at which most men begin to appreciate this problem. And most certainly everything possible should be done to keep the human element in industry before him and thus offset as far as possible the somewhat detached and materialistic attitude of mind that is so often found in those who concentrate their attention on pure and applied science.

It is not asserted that a training such as is outlined in the foregoing is essential for all industrial managers. We are discussing only the training of high-grade technical men who may be expected to become industrial leaders in a large way. There can be no doubt that many of the proposed courses of training that contain little or no science and engineering will be found of great value in training certain types of men. Schools of commerce have long been successful in training men for business with very little science, pure or applied, in their curriculum; and such courses modified by the introduction of a limited amount of pure and applied science should be of great value to a large number of prospective industrial workers. But such courses do not produce the engineering type of mind. They are not courses in engineering at all, but are often attempts to produce this type of mind by using other educational content and at the same time giving considerable attention to the practical aspects of industrial organization and management. If this can be done, then, as previously stated, lawyers can be trained without studying much law. And those who now so strongly advocate modifications in the engineering courses and the substitutions of large amounts of instruction in industrial relations would be the first to discover that the product of such curricula was not what they had expected.

Closer Co-operation Needed on the Part of Industry

And the industrial manager must learn that he has duties to perform which up to the present he has shirked or performed but poorly. For after the college has done all it can do for the prospective industrial worker he still is merely good material from which the industrial manager may, if he will, mold an efficient and intelligent industrial leader. The average industrial manager expects to receive from the college a full-fledged engineer or manager, while at the same time he would not think of permitting a newly-graduated doctor to remove his appendix. The technical schools should and can teach fundamentals, but the burden of adapting and specializing the graduate to fit any particular industry should rest squarely upon the shoulders of the industrial manager and of the industry where it rightly belongs. It should be said in all fairness that many progressive industrial managers have already recognized the truth of this statement as is shown by the special provisions now made by industrial concerns to adapt the college graduate to suit their specific needs. Closer co-operation is much needed along these lines.

Furthermore, these considerations are not the only ones to which the colleges must give heed. The primary object of the technical schools was to send out men who would be *useful to the industries*. Most of the technical colleges have not got far beyond this strictly utilitarian viewpoint and the demands of industry tend to keep this viewpoint constantly before them. Our national ideals, however, have changed greatly since technical colleges were first organized. A new industrial day has dawned in which profits, as such, are not the most important consideration, and industry is coming to be looked upon as a means of supporting human existence, not as a means of corporate profit. We have become more interested in men than in machines.

The Kind of Industrial Efficiency to Be Developed

Industrial efficiency we must develop, but the fruits of this efficiency must be for all if we adhere to our present national ideals of democracy. An efficiency that benefits the employer and not the employees, or an efficiency that builds up the state at the expense of the individual, is foreign to these ideals. If technical graduates are to take an active part in industrial management, and it seems assured that they will, the colleges will be remiss in their duty if they do not include in their course of instruction such work as will give their students some idea of the modern views of the distribution of the fruits of industry. Here is an educational problem and an educational content to be formulated regarding which little is said in the criticism of the technical graduate, though it is one of the most important of educational problems. "Where there is no vision the people perish," said the prophet of old, and this is as true today as it was thousands of years ago. Efficient industrial managers we must have; but if the republic is to endure we also must have industrial managers whose vision will be great enough to look beyond the petty requirements often laid upon the technical school for the man who, *while useful to his industry*, can also do something to make industry *more useful to all men*.

For after all, ideals and not technical developments move the world. The recent remark of a great industrial leader that if he had his way he would put business men at the headships of our colleges and universities shows a lamentable lack of knowledge of the principal purpose of such institutions. Technical and commercial efficiency we must have, and the problems of production must be solved. But it will avail us nothing if we cannot also solve the problem of human relations. Our business men and financiers cannot lay claim to much progress in solving this last problem. Yet it is the one great problem and one that requires not only industrial knowledge but high idealism and a love for humanity. It has been charged that the colleges and universities are too far removed from industry and the practical things of life. This may or may not be true, but it is sincerely to be hoped that there will always be in this land great institutions of learning that are not dominated solely by industry or industrial ideas, where great teachers will have an opportunity to prepare men not only for the industrial world that now exists, but will also be free to prepare them to build a better industrial world to come.

Michigan Leads U. S. in Paper Mill Growth

Michigan has led all other states of the Union in the growth of the paper industry during the past 5 years, as in this time 27 new mills have been constructed and placed in operation, increasing the number from 39 to 56. There are now 105 paper machines in service, as compared with 89 machines installed in 1917. Kalamazoo and Monroe are the centers of the industry in the state. Kalamazoo leads the country in the manufacture of book papers. Monroe leads in boxboard

Brittleness Developed in Pure Lead by Stress and Corrosion

It Has Been Known That Corrosion Induces Intercrystalline Brittleness—It Is Now Shown That Damage Is Accelerated by Accompanying Stress—A Method Is Noted of Making Large Columnar Crystals or Stalactites of Metal

By HENRY S. RAWDON, ALEXANDER I. KRYNITSKY and JULIUS F. T. BERLINER*

In A previous publication[1] it has been shown that the condition of intercrystalline brittleness sometimes found in lead by which the metal may be changed to the form of a granular powder is the result of selective corrosion of certain portions of the material rather than to an allotropic change, as had been previously stated by some investigators. The results obtained by Thiel[2] confirm those given in the publication referred to above. It was shown further that the readiness with which such intercrystalline brittleness may develop is a function of the purity of the metal and that by a selective corrosive attack of impurities existing as intercrystalline lodgments the change is brought about. By the use of suitable corrosive agents, even very high-grade lead can be made to exhibit intercrystalline brittleness to an appreciable extent.

Simultaneous Action of Tensile Stress and Corrosion

Lead, as cable sheathing and in other similar forms, is sometimes subjected to considerable tensile stress during its service. For this reason a series of experiments to demonstrate the influence of externally applied stress upon embrittlement seemed very desirable.

The material from which the specimens were prepared was of very high purity[3] (99.99 per cent) in order to minimize any effect caused by impurities in the material. It was cold-rolled into rods of $\frac{3}{8}$ in. diameter and then drawn to a 0.164-in. diameter wire. Specimens approximately 10 in. long were cut from the wire and annealed for 2 hours in an oil bath at 216 deg. C.

In the determination of the mechanical properties of lead, the results are influenced in a very marked degree by the conditions under which such properties are determined, particularly by the rate at which the load is applied. The ultimate tensile strength of the material to be used was determined by a "dead weight" loading by the addition of small weights, approximately 4 oz. each, to a container suspended at the free end of a specimen held in a clamp. A period of approximately 10 minutes was required for the addition of sufficient load to break a specimen. The material was found to have an ultimate strength (as determined under these conditions) of 1,705 lb. per sq.in.

The appearance of the fractured ends of a lead wire broken in this way is shown in Fig. 1. In this case, however, the specimen was loaded with a weight of only 710 lb. per sq.in. and a period of 12 days was required to cause fracture. In addition to the sharp "necking-down," a characteristic roughening of the surface for some distance back of the break occurred. The specimen also showed a trace of what appeared to be intercrystalline fissures,[4] in the roughened portion.

For demonstrating the effect of the simultaneous action of tensile stress and corrosion, a cylindrical glass container was fitted around the central portion of each specimen. The solutions used and the applied loads are summarized in Table I. In each case the corroding solution surrounded the lead specimen for a distance of approximately 1 in., and the surface of the liquid was covered with a thin layer of sperm oil to prevent excessive evaporation and also to minimize the accelerating effect of atmospheric oxidation. The loads applied to the specimens were arbitrarily chosen, one-tenth, one-fourth and one-third of the ultimate strength in tension, as previously determined, being used. The

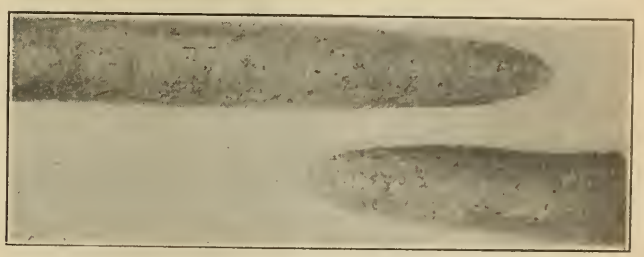

FIG. 1. PURE LEAD BROKEN AFTER HOLDING 710 LB. PER SQ.IN. FOR 12 DAYS. × 3

attempt was made to employ a maximum load of one-half the ultimate tensile strength of the material, but it was found impossible to use such a load on account of the flowing of the metal and subsequent breaking in the grips.

From the results summarized in Table I it will be seen that many of the specimens which were surrounded by the mildly corroding liquids failed from various causes before the completion of the test. In some cases fracture occurred in the grips on account of the gradual flowing of the metal at these points under a larger stress at these portions caused by the flattening of the material. The ability of lead to flow gradually under the continued application of a load which may be very much less than the "tensile strength" of the material is very characteristic and also well known.

In most of the specimens for which the test period was rather long, considerable localized corrosion occurred just above the oil layer. On account of the disturbance of the rack on which all the weighted specimens were hung, by reason of the breaking of specimens at different intervals and from accidental

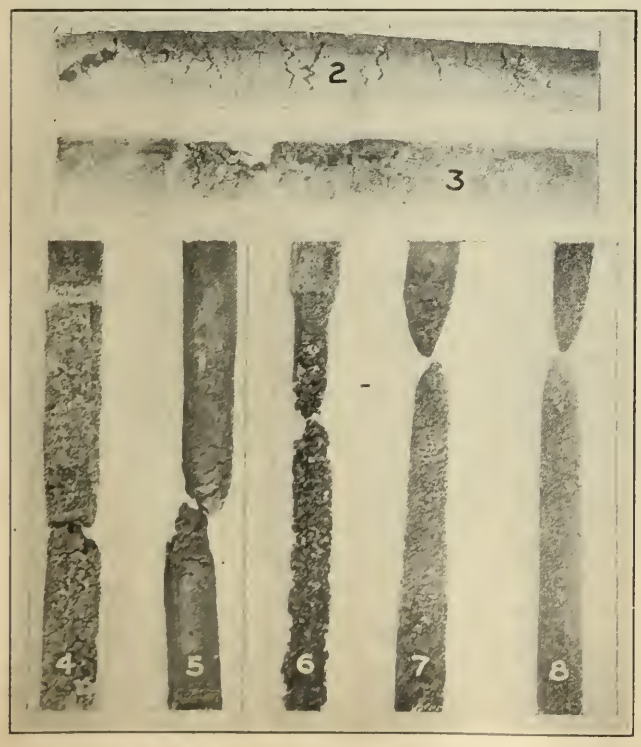
TABLE I. EFFECT OF THE SIMULTANEOUS ACTION OF TENSILE STRESS AND CORROSION UPON LEAD

Specimen No.	Liquid Surrounding Stressed Specimen	Load Applied to Specimen 0.164 In. Diameter, Lb.	Unit Stress Computed, Lb. per Sq.In.	Time Interval Before Fracture Occurred, Days	Remarks
1	Distilled water	3.6	170	...	Specimen intact; no evidence of embrittlement after 340 days.
2	Distilled water	9.0	426	...	Broke in upper grip after approximately 200 days.
3	Distilled water	12.0	568	...	Broke in 83 days—just above oil layer, no evidence of embrittlement.
4	N_2 aqueous lead acetate solution	3.6	170	...	Specimen intact; no evidence of embrittlement after 340 days.
5	N_2 aqueous lead acetate solution	9.0	426	...	Broke in 202 days, just above the layer of oil.
6	N_2 aqueous lead acetate solution	12.0	568	...	Broke early in the test period, record lost. No embrittlement.
7	N aqueous lead acetate	3.6	170	...	Specimen intact after 340 days, embrittlement started, intercrystalline fissures have formed.
8	N aqueous lead acetate	9.0	426	...	Broke in 192 days, just above the lower grip.
9	N aqueous lead acetate	12.0	568	117	
10	N_2 aqueous lead acetate solution + N_2 nitric acid	3.6	170	94	Fig. 4.
11	N_2 aqueous lead acetate solution + N_2 nitric acid	9.0	426	21	Figs. 2 and 3.
12	N_2 aqueous lead acetate solution + N_2 nitric acid	12.0	568	15	Fig. 5.
13	N aqueous lead acetate solution + N nitric acid	3.6	170	13	Fig. 6.
14	N aqueous lead acetate solution + N nitric acid	9.0	426	9	Fig. 7.
15	N aqueous lead acetate solution + N nitric acid	12.0	568	5	Fig. 8.

jarring of the liquid in the cups surrounding the lead samples, some of the specimens became covered with a slightly emulsified layer of lead acetate for a short distance above the surface of the oil layer. The difference in the rate of corrosion along the bar was great enough in two cases as to cause the specimen to fail in the upper part before the portion surrounded by the corroding liquid was appreciably attacked.

The results obtained (Table I) plainly indicate that embrittlement of lead quickly results when the metal is submitted to the simultaneous action of tensile stress and corrosion. Figs. 2 to 8 show the characteristic appearance of specimens after the attack. The fact that the fissures which form are intercrystalline was readily revealed by microscopical examination of longitudinal sections of broken specimens.

In general, the results of the tests indicate that while the application of a tensile stress powerfully accelerates embrittlement of lead, corrosion is of more fundamental importance in causing the embrittlement



FIGS. 2 TO 8. PURE LEAD BROKEN UNDER COMBINED STRESS AND CORROSION, AS NOTED IN TABLE I. × 3

to occur. The regularity in the rate at which failure occurred with respect to the concentration of the corroding solution and also to the magnitude of the applied stress suggests very strongly that after a sufficiently long interval of time the specimens subjected to the action of the very mildly corroding solutions would

FIG. 9. COARSE-GRAINED LEAD AFTER 42 DAYS IN 2N NITRIC ACID PLUS N LEAD ACETATE. NATURAL SIZE

behave in a similar manner if other conditions do not interfere. However, whether lead is sufficiently soluble in distilled water to permit failure by "intercrystalline brittleness" to occur is not apparent and can only be conjectured.

It is not to be concluded that embrittlement of lead always necessitates a corrosive attack of the metal. It has been known for some time by users of lead cables that overhead cables on bridges and similar structures which are subject to vibration must be supported in a special way so as to minimize the vibratory effect on the cable, otherwise embrittlement cracks will develop as a result of the stress conditions. Such cases have recently been described by Archbutt.[5] The intercrystalline character of cracks produced under such conditions, however, is not so evident as when corrosion is one of the factors which bring about their production.

Corrosion of Coarsely Grained Lead

The fact that the corrosive attack of lead is truly intercrystalline is shown in Fig. 9 in a very striking manner by the use of excessively coarsely grained material.[6]

In Fig. 9 is shown a 2-in. section of a lead "stalac-

[5] L. Archbutt, "Failure of Lead Sheathing of Telegraph Cables. Contribution to Synposium on Effect of Prolonged Application of Stress on Metals," *J. Faraday Soc.*, vol. 16, April, 1921.

[6] Some very coarsely crystalline bars in the form of icicles or stalactites were prepared by John R. Freeman, Jr., Associate Physicist, Bureau of Standards, thus: An iron rod was allowed to touch the surface of the molten metal and, after a sufficient amount of lead had solidified upon it, was slowly moved upward at a carefully controlled rate. By properly adjusting the rate at which the rod is moved a bar of lead resembling an icicle in shape may be produced, consisting of a relatively very small number of crystals. In some cases a single crystal may form the entire cross-section of the rod.

tite" after corrosion for 43 days in a nitric acid solution. It will be noted that the crystals, as seen on the end of the corroded specimen, are separated from one another by conspicuous "ditches," the width and depth of which can be readily observed without resorting to the use of the microscope. The chemical analysis of lead used indicated the composition to be as follows: Lead, 99.94 per cent; copper, 0.03 per cent; and antimony, 0.03 per cent. The depth and width of the intercrystalline "ditches" which form during corrosion appear to be related closely to the grain size and to be more prominent than might be expected from the small percentage of impurities in the metal. This suggests that, at least in the case of lead, the intercrystalline impurities may not be entirely responsible for the intercrystalline attack during corrosion.

Summary

The results obtained in the preceding experiments in connection with those previously described in the publication cited in footnote 1 indicate that lead is quite different from the other soft metals in its behavior upon prolonged corrosion. This metal, even of a very high degree of purity, develops intercrystalline brittleness when subjected to a corroding medium, particularly of an acid nature, for a considerable period of time. The application of an externally applied stress while subjected to the action of a corroding solution is a powerful adjunct in producing intercrystalline brittleness, as was exemplified in the case of lead. Specimens broken in tension under such conditions have an appearance characteristic of a brittle material. Examination readily shows, however, that only the "bond" between adjacent crystals has been affected; the grains themselves retained their ductility and other characteristic properties.

Sulphuric Acid Tank Leaks Caused by Wood Borers

By C. E. Cresse*

TANKS for holding sulphuric acid at the Chicago Heights plant of the Armour Fertilizer Works were built from North Carolina pine cut in the winter. The bottom of each tank was formed from 2 x 8-in. planks laid flat, and the sides and ends were made up by laying 2 x 8-in., 2 x 6-in., and 2 x 4-in. planks flat with the 2-in. edge next to the inside of the tank, which was lined with sheet lead about $\frac{1}{8}$ in. thick. Reference to Fig. 6, page 336, Chemical & Metallurgical Engineering, vol. 24, 1921, will give a clear idea of this method of construction.

Holes Not Apparent to the Eye

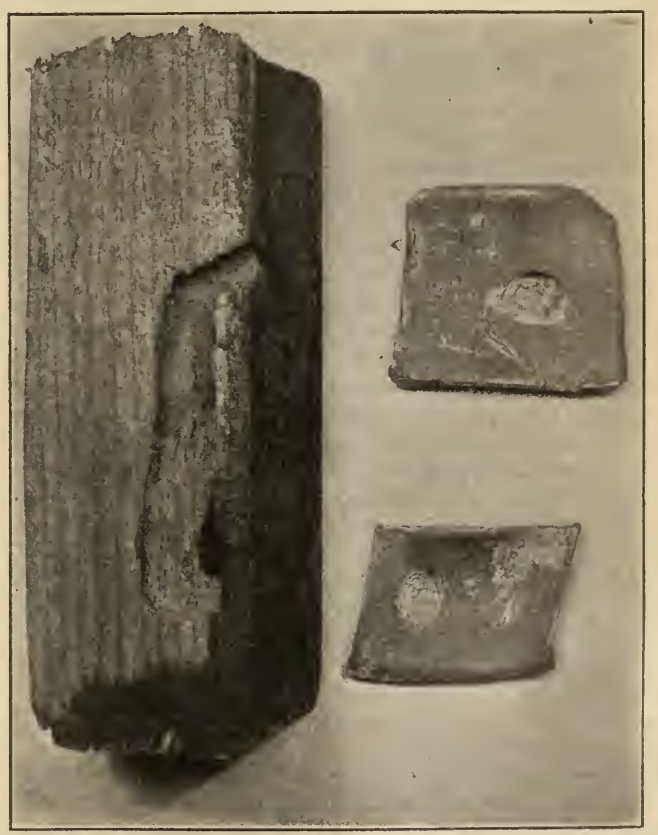
The tanks were filled with 50 per cent sulphuric acid in May, and when 5 weeks later they began leaking, the acid was drawn off and an investigation made. Considerable difficulty was encountered in locating the trouble because no holes were apparent to the eye on the interior lining. The approximate locations of the leaks were determined by the moist spots in the wood on the outside, the lead was cut and curled back and the work of the wood borer disclosed.

Specimens of the beetle were sent to a Washington government department, where it was identified as the Capricorn beetle, more commonly known as the Goat beetle or Sawyer worm. This Southern pine sawyer is named more technically the *Monohammus confusor*. Starting as an egg laid by the female beetle on the surface of the timber, he hatches into a borer. He feeds on the sapwood, weaving back and forth until grown to full size, when he mines deep into the heartwood and back to the surface again. Here he passes through a resting stage and is transformed into a long-horned beetle. Many kinds of forest trees are attacked by the borer with serious damage to the timber.

Timber Contained Many Borers

Evidently the timber from which these tanks were made contained a large number of borers. When they mined to the surface and encountered the lead lining of the tank the "goat" instinct was aroused and they proceeded to dine on the lead. All activity, "goat" and otherwise, ceased, however, when they tapped the sulphuric acid.

In the accompanying illustration are shown on the left the progress of the worm through the timber and the exit where it attacked the lead lining. On the right are photographs of the holes made by the borer on the outer side of the lead lining—i.e., next to the wood. The sharp tooth marks are plainly visible.



PHOTOGRAPH SHOWING PROGRESS OF THE WOOD BORER

On the left is shown the path of the worm through the wood and the exit where it attacked the lead lining. On the right are photographs of the lead lining on the side next to the wood, through which the worm also bored.

The action of wood borers causing leaks in acid tanks and chambers has been known for several years, but preventive measures are usually considered too late. It is recommended by the United States Forest Service that such wood be treated with creosote to kill these pests before it is employed for construction purposes.

American Chemists—A Statistical Study

By Gerald L. Wendt
University of Chicago

THE data given in the edition of "American Men of Science" for 1920 furnish the following facts relative to the distribution and education of the leading American chemists. The chemical profession still leads all others in the number of its representatives listed. Of about 9,500 men listed 1,852, or 19.5 per cent, are chemists, including biological chemists, chemical engineers, industrial chemists, physical chemists, etc. This is about 12 per cent of the 15,000 membership in the American Chemical Society. In point of age and eminence the list is headed by Dr. Charles William Eliot, president emeritus of Harvard University, born on March 20, 1834, who was assistant professor of chemistry at Harvard from 1858 to 1863 and professor of chemistry at the Massachusetts Institute of Technology from 1865 until his election to the presidency of Harvard in 1869.

Of particular interest are the 220 men who are designated with an asterisk in chemistry and are thus among the 1,000 "students of the natural and exact sciences whose work is supposed to be the most important." In the first edition of this compilation, in 1905, chemistry had 175 men among the thousand, or 17.5 per cent, and led all other sciences by a handsome margin. This lead has in the intervening 15 years been increased to 22 per cent. In the following study of these 220 men no individual names are mentioned, since the inclusion or exclusion of any particular name in this list is subject to a large error of personal choice. The statistics based on large numbers, however, are of value.

As would be expected, most of the men are between forty and sixty years of age. Divided into decades, the numbers are as follows: Eighty to ninety years of age, 3; seventy to eighty, 21; sixty to seventy, 37; fifty to sixty, 76; forty to fifty, 59; thirty to forty, 22; below thirty, 1; date of birth not given, 1.

The geographical distribution of these leading chemists shows a great preponderance along the northeastern coast. In the states bordering on the Atlantic from Massachusetts to the District of Columbia are 151, or 68.6 per cent. Listed by states in numerical order the distribution is as follows: New York, 55; Massachusetts, 25; District of Columbia, 21; Pennsylvania, 17; Connecticut, 14; Illinois, 13; California, 12; New Jersey, 10; Ohio, 10; Maryland, 6; Michigan, 5; Wisconsin, 5; Minnesota, 4; Missouri, 4; Kansas, North Carolina, Nebraska, Rhode Island and Virginia, 2 each; Delaware, Indiana, Iowa, Nevada, New Hampshire, South Carolina, Texas, Utah, British Columbia, 1 each. There remain twenty-two states with no leading chemist.

Doctor's Degrees Held by Leading Chemists

Of these 220 chemists seventy have honorary degrees, chiefly Sc.D. and LL.D. Of the 70 recipients of honorary degrees 3 have no other degrees whatever, 11 have a bachelor's or master's degree but no Ph.D., and 56 have both a bachelor's or master's degree and the Ph.D.

Only 149 of the 220 leading chemists have the Ph.D. degree, while 71 do not have it. Of the 149 who have the Ph.D. degree 56, or 37.6 per cent, obtained it in Europe. This is a large fraction, but it is rapidly diminishing. Of the 23 men born since 1880, only 3, or 13 per cent, have a European Ph.D., while of the remaining 126 born in 1880 or before, 53, or 42 per cent have a European Ph.D. The 56 Ph.D.'s granted by European universities are distributed as follows: Leipzig, 18; Göttingen, 15; Heidelberg, 10; Berlin, 3; Munich, 2; Strassburg, 2; Bern, Breslau, Freiburg, Hanover, Jena, and Zurich, 1 each. The 93 men who received the Ph.D. from American universities are distributed as follows: Johns Hopkins, 22; Harvard, 14; Yale, 13; Chicago, 10; Pennsylvania, 6; Columbia, 4; Massachusetts Institute of Technology, 3; Cornell, Illinois Wesleyan, Michigan, North Carolina, Stanford and Wisconsin, 2 each; Brown, California, George Washington, Illinois, Kansas, Lafayette, Minnesota, Ohio (Athens), Princeton, Toronto and Tufts, 1 each. (Two men have 2 Ph.D.'s each.) Thus 73 of 95 degrees were given by the endowed universities, and only 22 by the state universities. Of the 71 chemists who have no Ph.D. degree, 11 have honorary degrees and 42 have bachelor's or master's degrees, 11 have M.D.'s and 18 have no degree whatever.

The fact that one-third of our leading chemists do not have the Ph.D. degree is perhaps surprising. It should be remembered, however, that the list includes industrial chemists and thus a number of heads of large commercial establishments who have not themselves contributed to the science of chemistry. In addition, a number of names are of executive officers in the Chemical Warfare Service, U. S. Army, whose contributions are not strictly chemical. Finally, it should be noted this condition does not apply to younger men. Of the 141 men fifty years of age or over, 53, or 38.6 per cent do not have the doctorate degree; but of the 23 men under forty years of age only 5 do not have the degree. Of these, 2 are Englishmen, educated in England, where this degree is not regular. There remain only 3 men or 13 per cent, who do not have the degree. One of these was a Colonel in the C. W. S., one is an editor and one is a chemical engineer in charge of a large government laboratory.

Distribution of Bachelor's Degrees

The distribution of bachelor's degrees is also of interest. Among this group of 220 chemists 174 have bachelor's degrees, of whom 11 have two each. The 185 degrees are distributed among the universities as follows: Harvard, 22; Yale, 16; Massachusetts Institute of Technology, 15; Michigan, 9; Wisconsin and Columbia, 6 each; Cornell, Johns Hopkins and Pennsylvania, 5 each; Amherst, California, Ohio State, Toronto and Williams, 4 each; College of the City of New York, Kansas, Princeton and Wesleyan, 3 each; Edinburgh, Haverford, Illinois, Lafayette, Nebraska, New York, Rutgers, Stanford, Tufts and Worcester, 2 each; Beloit, Bethany (Kan.), Bowdoin, Brown, Buchtel, Bucknell, Case, Chicago, Cincinnati, Colorado, Dalhousie, Davidson, DePauw, Doane, Earlham, Georgia, Gettysburg, Grinnell, Hamilton, Hanover, Kentucky, Knox, Lehigh, Maine, Middlebury, Minnesota, Muhlenburg, North Carolina, Northwestern, Penn. State, Purdue, Rensselaer, Rhode Island, Swarthmore, Texas, Vanderbilt, Virginia, Washington and Lee, Westminster (Pa.) and Wooster, 1 each.

It is thus apparent that Harvard and Yale stand out both in graduate and in undergraduate work, while Johns Hopkins and Chicago predominate in graduate instruction and Massachusetts Institute of Technology and Michigan show undergraduate strength. Other deductions must be left to individual interest.

The Distillation of Coke-Oven Tar and the Recovery of Some of Its Products

An Outline of Current Practice in the Refining of Coal Tar and Its Principal Products of Commercial Importance—Description of Processes Involved in Recovery of Tar Acids, Naphthalene, Anthracene, Creosote Oils and Pitch

By WILBERT J. HUFF

THE successful results achieved by the use of coke-oven tar as a fuel in open-hearth steel furnaces have led to its extensive consumption in such furnaces, and since the majority of byproduct coke ovens are operated in connection with steel works, much of the tar is utilized as fuel near its point of origin. Coke-oven tar, however, compares very favorably with coal tar of other origin, and is admirably adapted to profitable distillation. This is, of course, very advantageous where all of the tar is available, as in the case of byproduct ovens operated primarily for the production of gas.

Coke-oven tar, or any coal tar, may be the source of a great many chemical products. However, most of these fall outside the province of the tar distiller, who finds it economical to confine his attention to the following chief products: Creosote oil, naphthalene, anthracene, carbolic and cresylic acids and pitch. Small quantities of light oil, ammonia water and pyridine are also recovered.

In the crude tar, these materials are so thoroughly incorporated with one another that it is necessary to have recourse to a process of fractional distillation and chemical treatment in order to separate them. The following fractions are usually separated:

(1) From atmospheric temperatures to 170 deg. C. (338 deg. F.): Products: Light oil, water, some pyridine,[1] some naphthalene.

(2) From 170 deg. to 235 deg. C. (338 deg. F. to 455 deg. F.): Products: Crude phenol, cresylic acid, naphthalene (crude), pyridine, creosote oil.

(3) From 235 deg. to 270 deg. C. (455 deg. F. to 518 deg. F.): Products: Creosote oil, naphthalene (crude).

(4) From 270 deg. to 315 deg. C. (518 deg. F. to 599 deg. F.): Products: Creosote oil, anthracene (crude).

(5) From 315 deg. to 355 deg. C. *supra* (599 deg. F. to 671 deg. F.): Products: Creosote oil, anthracene (crude).

In fraction 1, the water forms an immiscible layer which is readily separated. It contains some ammonia and its compounds, but the recovery of this is rarely undertaken save when the tar distillation plant is near a byproduct coke plant. The light oil may be pumped to the light-oil still of the coke plant to be rectified together with the light oil from the gas. The naphthalene contained in this fraction is thus taken care of in the regular coke-plant operation where the naphthalene appears in the still residues.

When the remaining condensates cool, they each give two phases, one an oil, brown or green in color, the other a solid, partially crystalline. The solid from fraction 2 is crude naphthalene. That from fraction 3 is largely crude naphthalene, although a little crude anthracene may appear. The solids in fractions 4 and 5 are called crude anthracene, although they are really a mixture of crude anthracene, carbazol and phenanthrene, together with a large number of less important hydrocarbons. When the solids have completely separated, the oils are drained off and the solids centrifuged or pressed to remove adhering oil. When sufficient distillate has been removed, the hot liquid pitch remaining is discharged directly into steel tanks or bays, where it is allowed to cool for subsequent handling and transportation.

The temperatures given represent vapor temperatures noted during the distillation and, because the character of a fraction cut from such a complex mixture varies with type of apparatus, these temperatures are only approximate. The practical tar distiller determines his cut points by observing changes in the character of his condensate. This should be remembered in reading the following pages.

Following is the distillation record[2] for a typical tar from a byproduct coke oven:

Fraction No.	Temperature, Deg. C.	Gal. per 1,000 Gal. Tar	Per Cent by Volume Referred to the Original Tar Vol.
1	Atmospheric—170	Oil—14.5	1.45
		Water—15.5	1.55
2	170–235	122	12.2
3	235–270	123	12.3
4	270–315	133	13.3
5	315–355	98	9.8
Residue and losses		494	49.4

Weight of residue, 57 per cent of original tar.

The following products may be obtained from such tar:

	Gal. per 1,000 Gal. Tar	Per Cent by Volume
Ammonia water	14.5 (0.6 lb. NH_3 est.)	...
Light oil[3]	15 (naphthalene not determined)	1.5
Tar acids	26	2.6

Crude Naphthalene	Lb. per 1,000 Gal.	Per Cent by Weight
170 deg.–235 deg. C. fraction	200	2.2
235 deg.–270 deg. C. fraction	48	0.6
Total	248	2.8

Crude Anthracene Cake[4]	Lb. per 1,000 Gal. — Without Chilling	Lb. per 1,000 Gal. — Additional Recovery Due to Chilling	Per Cent in Weight — Without Chilling	Per Cent in Weight — Additional Recovery Due to Chilling
270 deg.–315 deg. C.	46.5	9.4	0.47	0.095
315 deg.–355 deg. C.	93.0	9.4	0.95	0.095
Total	139.5	18.8	1.42	0.19

[1] The pyridine content is small and in this country its recovery is seldom undertaken.

[2] In interpreting tar analyses, it should be remembered that it is not possible to attain in tar analyses the high precision of most chemical analyses. Moreover, from time to time the composition of the tar changes somewhat due to variations in the operating conditions and the coal supply.

[3] The exact composition of these tar acids was not determined. The probable composition is crude phenol approximately 1 part, cresylic acid approximately 2 parts.

[4] The exact per cent anthracene was not determined.

Pure anthracene ($C_{14}H_{10}$) is a solid hydrocarbon which on oxidation gives anthraquinone, whose dihydroxy derivative is alizarine, an extremely important red dye. Anthracene is rarely obtained pure. Phenanthrene, carbazol, acenaphthene, fluorene, methylanthracene, chrysene, pyrene and a great many other hydrocarbons are intimately associated with it and possess so many properties in common with it that the isolation of pure anthracene is rather difficult. The refined anthracene of commerce contains about 80 per cent of anthracene.

Government statistics[5] for 1920 show a total production of almost three million pounds of crude anthracene (25 per cent) and 100,000 lb. of refined anthracene (on the basis of 100 per cent). This is somewhat less than the requirements of the dye industry caused principally by the fact that there is no great demand for hard pitch in the American market; consequently, much of the anthracene is not distilled out of the pitch.

Carbazol [$(C_6H_4)_2NH$] is found intimately associated with anthracene and although always a constituent of crude anthracene cake, it is not generally isolated by the tar distillers. Dye companies purchasing anthracene sometimes insist on a content of anthracene not too high (maximum about 55 per cent), thus insuring a supply of carbazol as a byproduct of the anthracene purification process. Carbazol is the source of some very important dyestuffs, among which are carbazol blue and carbazol yellow.

Naphthalene ($C_{10}H_8$) is the most familiar pure product of the tar distillery. Its uses are many and constantly increasing. In the field of dyes it serves as a starting point for all the phthalein colors, such as eosine, erythrosin, etc., a great many azo colors containing naphthols. The chemical uses for naphthalene have been stimulated in the past few years by the discovery of a catalytic process whereby naphthalene is oxidized by air to valuable intermediate products, chiefly phthalic acid.[6] The deficiency in the supply of anthracene is being made up in part by synthetic anthraquinone prepared from phthalic acid.

While it is probable that these uses for naphthalene will increase, such an increase will probably not absorb the complete production of naphthalene, and studies are in progress to extend the uses. One of the recent developments is the hydrogenation of naphthalene to compounds such as tetra-hydro-naphthalene and deca-hydro-naphthalene. A mixture of these gives a liquid oil which absorbs oxygen and becomes sticky, and is offered as a turpentine substitute.[7]

The possibility of developing a use for naphthalene such as driving internal-combustion engines is of interest. For this purpose it is of course not necessary to purify the commercial recrystallized material, since this is a nearly pure chemical compound of definite boiling point, practically free from gum- and resin-forming materials. To permit easy handling it is formed into balls and is fused just before it enters the engine.

Naphthalene when mixed with pitch serves to lower the melting point and decrease the viscosity. Consumers of liquid fuel oil who wish to obtain this oil by distillation of tar to a very soft pitch may carry the distillation to a harder pitch, thus obtaining more liquid oil, and cut back the pitch to a softer grade again by adding to it crude naphthalene.

Tar Acids. Coal tar contains an extremely important group of compounds which are acidic in nature—i.e. they are capable of forming water-soluble compounds when treated with caustic. They redden litmus paper, are themselves soluble in water to varying degrees, and possess important antiseptic and germicidal properties. The number of these tar acids is probably large, and they appear to some extent in all the fractions, but are at the highest concentration in what is sometimes called the carbolic fraction (i.e., 170 to 235 deg. C.) and this is the only fraction regularly washed for tar acids. This contains chiefly only phenol and cresols, and these two compounds are the only ones separated by the tar distiller, the higher boiling tar acids being permitted to remain in the creosote oil, where they form important agents for the protection of wood.

Perhaps the greatest demand for phenol will come from the manufacture of the synthetic phenol-formaldehyde resins. These resins, which generally resemble hard rubber, have an enormous variety of uses in the technical and industrial world. A very familiar product containing such resins is the phonograph record. These resins can consume an enormous amount of phenol (or cresol), possibly millions of pounds, provided the phenol can be obtained at a favorable price.

Another use which consumes a large quantity of phenol is the manufacture of disinfectants and germicides. Carbolic acid and carbolated products are too well known to require comment. Prior to the introduction of phenolic resins, the chief commercial outlet for phenol rested upon its antiseptic and germicidal properties.

Pure cresol of commerce is a mixture of three isomeric compounds having the formula $C_6H_4OHCH_3$. The tar distiller generally does not endeavor to isolate any one of the cresols pure. However, ortho-cresol may be separated from phenol and the other cresols by fractionation through a good column, and for that reason can be purchased pure. Neither meta- nor para-cresol is regularly offered for sale in its pure form, since it is impossible to separate these by fractionation. Instead a mixture, known as meta-para-cresol, is offered.

The cresols are more efficient bactericides than phenol and at the same time are less poisonous, consequently they are preferred for many uses. The important formaldehyde condensation products known as the synthetic phenolic resins can be prepared from the cresols as well as phenol. The cresols play an important part in the manufacture of certain coal-tar colors and are often prepared pure by the dye manufacturer.

Tar Bases. In contrast with the acidic compounds found in coal tar there exists a group of basic compounds, containing nitrogen, of which the most important are pyridine and its derivatives. These are extracted from certain of the tar oil fractions by washing with dilute sulphuric acid.

Pyridine, however, is rarely isolated pure. Commercial grades generally contain a little water and higher boiling bases. The more volatile fraction of commercial pyridine (115 to 160 deg. C.) is used as denaturing alcohol because of the nauseating taste and

[7] *Chem. Zentral.* (1919), vol. 4, p. 688. A number of patents covering the preparation of hydro-naphthalenes have been applied for—e.g., International Specifications 147,474; 147,476; 147,478; 147,580 to G. Schroter, Berlin.

mell which it imparts. The higher fractions are used as solvents in purifying anthracene.

Creosote Oil and Pitch

By far the greater percentage of the compounds in coal tar are not worked up for isolation in the pure state, but are sold as constituents of creosote oil or pitch, and it is in these products that the bulk of the tar distiller's business is done. Accordingly uses for these products are extremely important to the tar distiller.

Creosote Oil. The term creosote is used in a very broad sense in commercial practice and includes many products which do not have their origin in a byproduct coke plant. In this article the term "creosote oil" will be applied to the residual oils obtained after the crystallization of the naphthalene and anthracene and extraction of phenol and cresols. Such oils form high-grade agents for the preservation of wood or almost ideal liquid Diesel fuel.

Certain purchasers require a creosote containing more naphthalene than the above oil contains. This furnishes an additional outlet for the crude naphthalene, which can be added as desired. The demand for creosote the last few years has been so great that much low-grade foreign material has been incorporated with coal-tar distillates. A favorite mixture is coal tar 20 per cent, coal-tar oil 80 per cent. Mixtures containing water-gas tar are also employed.

Pitch. Since the amount of pitch obtained from coal tar is very large (about 50 to 60 per cent by weight of the tar), it is very important to so conduct the distillation that this shall be marketable at its maximum value. For this reason tar distillers generally run to a certain grade of pitch, rather than to a certain percentage of oil, or to a certain vapor temperature.

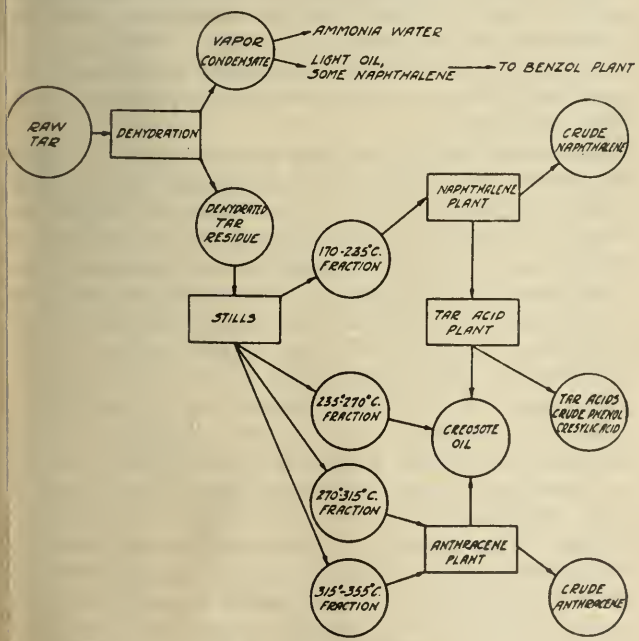

FIG. 1. FLOW DIAGRAM OF THE PROCESS FOR REFINING TAR

Pitch may be graded into three groups: (1) Soft, (2) medium, and (3) hard. These grades of pitch have a great variety of uses, among which may be mentioned:[8]

(*a*) Roofing.—This use is so well known that it requires only passing mention.

(*b*) Waterproofing.—Tunnels, bridges, underground construction in general makes important use of pitch as a waterproof binder.

(*c*) Paving.—Coal-tar pitch has had wide application in the construction of many types of paving. The use of soft pitch as a binder in concrete and tar macadam roads has been extremely important lately. Block and brick pavements use pitch as a filler.

(*d*) Paints and Protective Coatings.—Solutions of pitch in coal-tar solvents are used for iron and steel, for acid-proofing and alkali-proofing, and for waterproofing.

(*e*) Pitch Coke.—A comparatively recent development is the demand for pitch coke as a source of carbon for the electrochemical industries. This promises to furnish an outlet for hard pitch.

(*f*) Miscellaneous.—A great many other uses may be mentioned such as core compounds for casting, as a briquet binder, as a pipe dip, as an insulating medium for electrical purposes and many other purposes.

The exact specifications for the pitches which are to be used for these purposes vary from purchaser to purchaser and are supplied by the purchaser, so they cannot be conveniently given here.

The complete production of pitch may be utilized in the coke plant. A brief discussion of this will be found on a later page.

Processes Involved in the Refining of Tar

The processes involved in the refining of tar take the sequence shown in Fig. 1.

Dehydration. The first process in the distillation of tar is that of dehydration. Thick layers of crude tar if suddenly heated will foam and spatter disastrously because of the explosive formation of steam from water droplets dispersed through the tar probably as in an emulsion. To avoid this, the tar is sometimes dehydrated in special apparatus where only thin films are exposed to the source of heat, which may be indirect. In this, the tar is gradually heated until the vapor temperature reaches 170 deg. C., thereby removing most of the water and free ammonia, together with a little naphthalene and a small amount of tar bases and oil.

In a tar distillery operated in conjunction with a byproduct coke plant, the oil is run to the light oil plant. The naphthalene will of course appear in the still residues from the light oil plant.

The Carbolic Oil Fraction. Naphthalene. The sequence of the operation upon the first or carbolic oil fraction (170 to 235 deg. C.) is indicated in Fig. 2.

The hot dehydrated tar is run to the stills, where it is further heated and the condensate evolved collected in appropriate fractions.[9] The carbolic oil fraction (170 to 235 deg. C.) first appears. This contains the phenol, the cresols and a large part of the naphthalene. Some pyridine is also present in this fraction. Upon cooling to atmospheric temperatures the oil is usually converted into a semi-crystalline mass which does not flow satisfactorily. For that reason it is pumped from the receiver while still warm and forced into the naphthalene crystallizing pans. Here it is allowed to remain at atmospheric temperature for from 3 to 5 days. The oil, generally brown in color, is then drained as completely as possible. The naphthalene crystals still entrain a large amount of oil, so these are shoveled by hand from

[8] Weiss, *J. Ind. Eng. Chem.*, vol. 8 (1916), p. 841.

[9] It is beyond the scope of this paper to consider in detail the construction and operation of the stills.

the crystallizing tanks and wheeled to the centrifuge, where much of the remaining oil is removed. The crude naphthalene is washed upon the centrifuge with a jet of cold water (about 18 deg. C.). It is then sufficiently pure to meet many specifications for crude naphthalene and may be sold as such. It is coarsely crystalline and somewhat oily, and generally possesses a dirty light brown color. Its melting point varies, but is generally well above 60 deg. C. The impurities are water, oil, tar acids and tar bases.

This crude naphthalene is often further purified. The first operation is recrystallization. The naphthalene is melted and again run into shallow pans. After standing for a few days, the crystals are centrifuged and washed with a stream of cold water. This recrystallized naph-

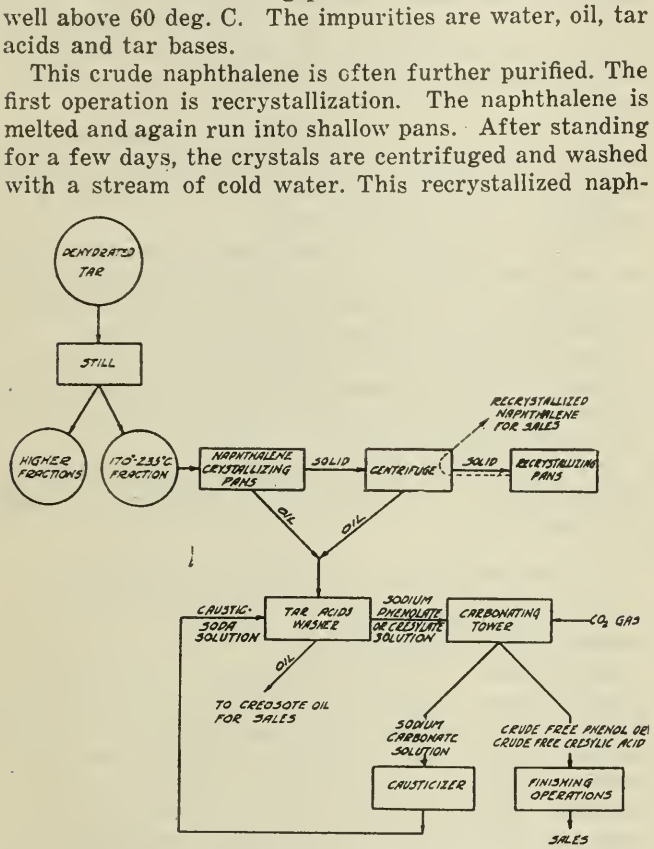

FIG. 2. FLOW DIAGRAM OF THE PROCESS FOR REFINING THE CARBOLIC FRACTION (170 TO 235 DEG. C.) OF TAR

thalene is still brown in color but much lighter than the crude grade described above. The melting point may be raised to 76 deg. C. or higher. The impurities are very much reduced, but still of the same nature as those associated with the crude naphthalene described above.

This recrystallized naphthalene can be converted into pure white naphthalene for balls and flakes by a very simple process. However, most tar distillers do not carry out this final purification, so it will not be described here.

The important control tests are: (1) Dry salt test for determining the content of naphthalene in an oil, (2) melting point tests for the quality of the naphthalene, and (3) distillation of the naphthalene. Water, if present, is also determined.

Recovery of Tar Acids. Many tar distillers do not isolate the tar acids as such, but sell instead the oils containing the tar acid. There are a number of modifications of tar-acid recovery, one of which is as follows:

The drain oil from the naphthalene pans and centrifuge used on the 170 to 235 deg. C. fraction is allowed to stand to settle out any ammonia liquor which it may contain, then is run into a suitable washer equipped with agitators. Here it is brought into intimate contact with a solution of caustic soda having an initial specific gravity of about 1.10 or containing approximately 8 pe cent NaOH. The total amount of caustic required de pends upon the tar-acid content of the oil and is dete mined by shaking a sample with increasing amounts c caustic until the oil volume no longer contracts. Fo tar of the analysis given above, this will not excee 140 gal. of 8 per cent caustic soda per 1,000 gal. c raw tar.

The tar acids consist mainly of phenol and the cresol and it is generally advisable to separate these, for i normal times the phenol is of higher value than th cresols. This separation is accomplished by takin advantage of the fact that phenol is a stronger aci than any of the cresols. In the presence of insufficien alkali the phenol will combine with the alkali, whi the cresols remain free, or if to cresol already combine with caustic (i.e., sodium cresylate), there is added a oil containing phenol, the phenol will drive out th cresol from its combination and form sodium phenolat instead. The process of washing which utilizes th property of competing and exchanging is known a the "interchange" process and is applied somewhat a follows:

Interchange Process for Separating Phenol Fro Cresols. To the charge of fresh oil in the agitator the is added less caustic than is necessary to combine wit all the phenol. (The correct amount can be determine by analysis. The probable ratio is 1 part of phenol t 2 parts of cresol, and the probable caustic use is abou one-third the total requirements.) The water-solub sodium phenolate formed is then drained into the phenc ate storage and a fresh portion of caustic added. Th will combine with some phenol and some cresol and held for "interchange" in the "interchange" storag A third and final portion of the caustic is placed upo the oil. This combines with the remaining cresols a is drained into the cresylate storage. When a secon lot of oil is to be washed, the phenol is extracted wi a portion of the caustic as before and is carried to th phenolate storage.

Meanwhile the chemist has ascertained the compos tion of the tar acids in the interchange storage tank This interchange liquid is run upon the washer a thoroughly agitated, then drained into an interchan storage tank until its composition has been ascertaine If the phenol content has risen to a crystallizing poi of 15½ deg. C., it has been converted into substantial pure phenol and is sent to the phenol storage. If no it is held for further interchange. Meanwhile a thi washing with fresh caustic is under way. The resulti product is reserved in a second interchange stora tank for analysis and is held for interchange or sent the cresylate storage depending upon the chemist's r port. The fourth and last wash is sent to the cresyla storage. The important control test in this process the determination of the crystallizing points of the t acids. Commercial coal-tar phenol crystallizes at 1 deg. C., while coal-tar cresol, substantially free fro phenol, does not solidify at —80 deg. C., so it is n difficult to interpret the test and apply it to the inte change process as described above.

In some tar distilleries phenol and cresylic acid a separated without resort to the interchange proces Less caustic than is necessary to combine with the e tire phenol content is employed for the first was which is of course practically pure phenolate. The r maining tar acids are extracted by a second wash. T

ixture of phenol and cresylic acid subsequently obained from this second wash is distilled through a olumn and the first or phenol fraction collected sepately. However, the interchange process is preferred, specially in the larger tar distilleries.

The washing process demands efficient agitation, for he caustic soda solution is immiscible with and slightly eavier than the oil. The mixture should be kept warm 30 deg. C., for example). If too hot, the extraction is ncomplete; if too cold, naphthalene may separate from he oil and cause trouble, for the tar acids aid in keepng naphthalene in solution and their removal permits he oil to deposit more naphthalene. The agitation is ontinued for from an hour to an hour and a half.

Decomposing the Phenolate and Cresylate.—The henolate or cresylate is then allowed to settle thorughly in order to free it as far as possible from he oil. The aqueous phenolate or cresylate is drawn off ntil an emulsion of oil and water appears in the sight ox. To assist in the further removal of oil, the phenolte or cresylate is allowed to remain in the appropriate torage tanks until needed and care is taken not to mpty these tanks completely when feeding the carbonting tower. An oily layer gradually collects at the urface of the storage and this must, of course, be leaned out at rare intervals.

From the storage tank the phenolate or cresylate is assed to the top of the carbonating tower.[10] Here it neets in counter-current a stream of gas containing arbon dioxide.

Carbon dioxide is a much stronger acid than either henol or the cresols and consequently combines with he sodium compound to form sodium carbonate, at the ame time liberating the phenol or the cresylic acid.

The gas, which is generally high CO_2 flue gas from oke-fired steam boilers, is purified by passing it through dust separator and washer. The washer may be a ower packed with limestone chips over which a stream f water flows counter-current to the gas current. This emoves sulphur dioxide and a little hydrogen sulphide vhich, if not removed, would gradually convert the odium salts to sulphate, which is worthless, since it annot be recausticized.

Often a flue gas of sufficiently high CO_2 content is not vailable. In such cases, it is generally the custom to uild a special coke-fired furnace for the production of he CO_2. The efficiency of the furnace may be increased y adding limestone to the coke charge.

At the bottom of the carbonating tower there is disharged a two-phase mixture consisting of spent liquor an aqueous solution of sodium carbonate) and subtantially insoluble free tar acid. This mixture is passed hrough two separators in series, the spent liquor being rained to the sodium carbonate storage while the phenol nd cresylic acid is run into an appropriate receiver for ettling. Here it is permitted to remain for several ours to remove the entangled spent liquor. From these ettling receivers the tar acid is run in measured quanities to a lead-lined finishing tank to be treated with measured amount of sulphuric acid. (Generally 60 eg. Bé. or 77 deg. sulphuric acid, sp.gr. 1.7, supplied rom an acid tank above.) It is necessary to use this acid because complete decomposition of the sodium phenolate or sodium cresylate does not take place in the carbonating tower. The sulphuric acid also aids in the removal of water. The acid is added carefully until the mixture changes blue litmus paper red. The tar acid is then tested for its water content in the laboratory, and in case the content is found to be greater than 15 per cent more sulphuric acid is added.

When the tar acid is properly finished, it is separated from the waste sulphuric acid layer by draining this through the sight box. The waste sulphuric acid is run into the waste storage. The crude cresylic acid generally contains some phenol, and it is often redistilled. The still is equipped with a good column, since the cut between phenol (b.p. 184 deg. C.) and orthocresol (b.p. 188 to 191 deg. C.) is a close one. A receiver for still residues must be provided, for the still cannot be run completely dry. The still residues are subsequently reworked and may yield as much as 80 per cent cresylic acid, the remainder being pitch and loss. A holder for pitch is also provided. Cresylic acid pitch has no special value and is mixed with the regular coal-tar pitch.

Before shipping cresylic acid, it is submitted to air blowing to "sweeten" it by driving out the hydrogen sulphide which it generally contains. It is then ready for sale.

In order to render this process of extracting tar acids economical, it is necessary to recausticize the sodium carbonate. A high-grade quicklime is used for this purpose. When a special carbon dioxide kiln is used, this produces a lime which can be used in the causticizing.

The oil which has been washed for tar acids is drained free from entangled cresylate solution. It may then be washed for pyridine or again worked up for naphthalene. With naphthalene sales at their present low point, the most economic disposal would probably be to run the drain oil into the creosote and keep the naphthalene in solution by the addition of anthracene drain oils. The 235 to 270 deg. C. fraction generally contains so small an amount of tar acids that it is not worked up for these. It is, however, often worked up for naphthalene. At present, it would probably be pumped into the creosote oil.

Redistillation.—Under certain local conditions it is best to submit the fractions containing tar acids and naphthalene to redistillation in order to concentrate these products before submitting the oils to the crystallizing and washing processes described above.

Anthracene Oils.—The fractions taken above 270 deg. C. (viz., 270, 315 deg. C. and 316 to 355 deg. C. *supra*) deposit crude anthracene upon cooling.[11,12] The process of extracting this is very similar to the crude naphthalene process, save that artificial cooling is sometimes resorted to in order to increase the anthracene recovery.

Crude anthracene is dark green to brown in color and possesses a pasty crystalline form. It generally separates in small crystals which hold considerable oil, the whole giving a buttery appearance very familiar to tar distillers. To separate these crystals from oil is some-

[10]In some tar distilleries the phenolate or cresylate is decomosed by the addition of sulphuric acid. This process, while less xpensive to install and more simple to operate, involves higher roduction costs, since the sodium sulphate produced is practially worthless and must be thrown away, necessitating the purhase of fresh caustic for each washing for tar acids. It is, herefore, generally used only in small recovery plants and will ot be described here.

[11]There is of course no sharp temperature break at which the presence of crude naphthalene ceases and the anthracene solids appear. The oils show a transition in which the content of crude naphthalene progressively declines while the content of the constituents of crude anthracene rises.

[12]The highest temperature attained during distillation varies considerably. The pitch, if overheated, may coke. To obviate this danger, a gas or steam is generally blown through the charge in the last stages and vacuum may be applied.

times difficult. A filter press is generally employed for this purpose.

The pressed crude anthracene cake still contains considerable oil, together with a large amount of other impurities such as carbazol, phenanthrene, acenaphthene, etc., which are solid at ordinary temperatures. The anthracene content is relatively low and may render the product unmarketable as such. It is then necessary to recrystallize it.

This is done by dissolving the first crude anthracene in hot naphthalene drain oil from the 170 to 235 deg. C. fraction. If redistillation of naphthalene oils is practiced, a light, clean redistilled drain oil is used. An excess of the hot oil is mixed with anthracene at a temperature of about 80 deg. C. The proportions sometimes used are 1 ton of pressed anthracene to from 500 to 600 gal. of oil. When all the anthracene has gone into solution in the hot oil, the mixture is permitted to cool to about 20 deg. C. The oil and crystals are then run upon a centrifuge for separation. The crystals are spun until thoroughly dry, washed with cold water, and bagged for shipment. They may contain from 30 to 50 per cent of anthracene. The residual oil is added to the creosote.

With changing local conditions, it is sometimes advisable to depart from the above practice somewhat. There sometimes appears between the naphthalene and anthracene fractions an intermediate fraction whose solids are so impure that they are not worth working up. This fraction is run directly into the creosote. Just above this there may be a fraction which gives a high quality of anthracene (as much as 35 per cent anthracene or higher) merely upon cooling and filtering. This may comprise as much as three-fourths of the remaining anthracene fraction. Still higher there may be a fraction which gives only a low-grade anthracene upon filtering and which must therefore be crystallized from hot naphthalene drain oil in the manner previously described.

Creosote Oil.—The character of the creosote oil ma be controlled to some extent by the omission of certai fractions and the inclusion of others, by the addition o omission of crude naphthalene, or of the carbolic o fractions which have not been treated to remove th tar acids. In this manner it is possible to obtain cre sotes capable of filling many widely different specifica tions.

At the present time fuel oil is abundant and not to expensive. However, the time is not far distant whe our dwindling oil reserves will probably compel th utilization of tar distillates as a source of liquid fuel Indeed, those companies which are at present adva tageously situated in respect to a suitable coal suppl are in a position to obtain such distillates today at price which compares favorably with fuel oil.

Pitch.—The pitch obtained by distilling oil from ta at vapor temperatures higher than 360 deg. C.[13] is ge erally a hard pitch. It is of course a simple matter manufacture a softer grade by stopping the distillatio at an earlier stage, and by careful regulation secu any commercial grade of pitch.

At a coke plant run in conjunction with a steel work it is generally not necessary to depend upon sales fo the disposition of pitch. Thus, with a tar having th analysis given, the distillation may be stopped at th end of the 235 to 270 deg. C. fraction, leaving a so pitch residue which can readily be liquefied by stea heating, and therefore in every way suitable for use a an open-hearth fuel in place of raw tar, provided onl suitable provision for steam preheating be supplie The oils, naphthalene and tar acids recovered by suc a distillation will total about 26 per cent of the volum of raw tar distilled and represent some of the mo valuable products of the tar distillery.

Iron Ore Mined and Shipped in 1921 Estimated by U. S. Geological Survey

The iron ore mined in the United States in 1921, exclusive of that which contained more than 5.5 per cent of manganese, is estimated at 29,547,000 gross tons, a decrease of 56 per cent as compared with the output in 1920. The shipments of ore from the mines in 1921 are estimated at 27,009,000 gross tons, valued at $89,688,000, a decrease in quantity of 61 per cent and in value of nearly 69 per cent as compared with the shipments in 1920. The average value of the ore per gross ton at the mines for the whole United States in 1921 is estimated at $3.32; in 1920 it was $4.11. The stocks of iron ore at the mines, mainly in Michigan and Minnesota, apparently increased from 11,378,794 gross tons in 1920 to 13,872,000 tons in 1921, or 22 per cent.

The output of iron ore in 1921 was the lowest since 1904, when 27,644,330 tons was mined.

The accompanying table shows the quantity and value of the iron ore mined and shipped in the United State by the principal producing districts. The figures fo 1920 are final; those for 1921 are subject to revisio

ESTIMATE OF IRON ORE MINED AND SHIPPED IN THE U. S. IN 1921

District	Ore Mined, Gross Tons		Ore Shipped, Gross Tons		Value	
	1920	1921	1920	1921	1920	1921
Lake Superior	57,945,049	25,394,000	59,677,331	23,155,000	$253,620,578	$81,091,000
Ala., Ga., N. C., Tenn., Va	6,766,794	3,022,000	6,702,730	2,946,000	19,330,818	6,343,000
N. J., N. Y., Pa.	2,085,959	668,000	2,096,321	444,000	10,266,130	1,278,000
Western	740,226	429,000	740,637	429,000	1,460,968	839,000
Conn., Md., Mass., Mo.	66,437	34,000	64,422	35,000	327,833	137,000
Total	67,604,465	29,547,000	$69,281,341	$27,009,000	$285,006,327	$89,688,000

French Production and Supplies of Naval Stores

Latest estimates indicate that the French productio of naval stores has not been as seriously affected by th summer droughts as was previously predicted, accor ing to information from Consul Jaeckel, of Bordeau printed in the Jan. 2, 1922, issue of *Commerce Report* The total production for 1921 is estimated at 31,0 tons of turpentine and 105,000 tons of rosin, pitch, et or 4,000 tons less turpentine and 15,000 tons less ros than in 1920.

Estimated stocks of naval stores held by merchan and distillers in the Bordeaux region total 1,000 to of turpentine and 6,800 tons of dry products. Th estimated amount in France at the close of 1921 wa 7,000 tons of turpentine and 30,800 tons of dry product

Colloidal State in Metals and Alloys. II—Crystallization

Primary Crystallization of Pure Metal Consists of the Coagulation of Very Tiny Crystalline Particles From a Molten Isocolloid—Recrystallization Consists of a Migration of Like Particles Across a Finely Dispersed Solid Mother Liquor Called the Amorphous Phase*

By JEROME ALEXANDER
President, Uniform Adhesive Co., Brooklyn, N. Y.

BEFORE considering the effects of the mechanical and heat treatment of metals and mixtures of metals (alloys), let us first try to follow mentally what happens upon the slow cooling of a hot saturated solution of a crystalloid salt—sodium chloride, for example, since it has no water of crystallization. As the kinetic energy of the system drops and the capacity of the water to maintain the salt molecules (or their ions) in motion diminishes, some salt molecules are extruded as it were from the solution, only to be dissolved again while others are extruded; for there exists a condition, not of static but of kinetic equilibrium, varying with the temperature.

Crystallization of Salt Solutions

If, however, a number of salt molecules are extruded in such a position and so close to one another that they may cohere—i.e., within the radius of molecular attraction—they may form a crystal nucleus, or "crytallogen," which in proportion to its size will tend to take from the cooling solution more extruded molecules than it gives back. Such dominant nuclei tend to form on the relatively cooler walls of the containing vessel or on any added nucleus or foreign surface providing a "rear guard." Quick cooling produces more extruded molecules per unit of time, and agitation tends to bring the extruded molecules into contact; therefore both these factors tend toward the formation of more numerous and smaller crystals. Where large crystals are desired, it is the practice in chemical works to crystallize in large tanks, which are carefully insulated and left undisturbed for weeks.

Extreme care is necessary to grow large perfect crystals from solution, the temperature being controlled within very narrow limits to maintain the slight degree of supersaturation at which no new nuclei or spontaneous crystals will form and yet the seed crystals (or large added nuclei) will grow. R. W. Moore[1] has grown clear, perfectly developed crystals of rochelle salt 3 in. long, the process taking about a month in a thermostat sensitive to about 0.01 deg. C. Of particular interest is his statement that crystals grow faster near the bottom of the crystallizing vessel than at the top, for this is evidence of a gravitational accumulation of molecular groups (nuclei or "crystallogens") at the bottom quite analogous to the separation of the particles in colloidal solutions, as demonstrated by Perrin.

Crystallization continues until there is reached the kinetic equilibrium corresponding to the final temperature; and we have discrete crystals of sodium chloride bathed in a mother liquor containing a residual amount of salt in solution or true crystalloid dispersion. Impurities tend to collect in the mother liquor, and if they are protectors (in the colloidal sense) may inhibit or modify crystallization as they accumulate, as is the case with molasses, for example.

Crystallization of Pure Metal

Even with pure metals under the best conditions, the path of crystallization is not as smooth as is the case with salt solutions, but is beset with complicating factors. There is no foreign restraining solvent, the viscosity is great, the attraction between the closely packed metal molecules is tremendous, and the metal soon forms a hard skin so that the interior crystals are formed under pressure or strain. With some metals there may be formed a geode-like center, where slower cooling and lessened or more equalized strain may result in the formation of large well-developed crystals.

But the metal seldom reaches the crystallization equilibrium, toward which it strives, for the enormous increase in viscosity which accompanies its rapid loss of heat prevents the aggregation tendencies of the metal molecules from entirely establishing themselves, and there results a mass of metallic crystals embedded in a finely dispersed solid metallic "mother liquor," the so-called amorphous phase.

The amorphous phase is colloidal, as its name, appearance and properties indicate, and contains a mixture of submicroscopic crystals or crystal fragments with unoriented or random clusters, possibly in the form of isotropic globulites; for the globulitic form, according to many investigators, seems to be a precursor of the crystalline condition. As stated in the first article in this series, at higher temperatures, before visible crystallization occurs, the whole metal probably exists as an isocolloid. The extent to which this state is altered in the direction of a visibly crystalline mass, embedded in a colloidal matrix, depends largely upon the speed of chilling. In impure metals and in alloys the composition of the phases and the presence of substances which hasten or inhibit crystallization are important factors.

Von Weimarn holds the view, in which the writer does not concur, that all molecules and molecular groups are crystalline, that crystallinity is the only internal state of matter and that in general no amorphous substances exist in nature. This view would give to the words "amorphous" and "crystalline" significations they do not at present possess. Besides the X-ray spectroscope shows[2] that many organic colloids, such as gelatin and starch, and also some inorganic colloids (silicic acid

*Part I, on Molten Metal, appeared in Chemical & Metallurgical Engineering, vol. 26, No. 2, p. 54, Jan. 11, 1922.

The present series of papers was written mainly in the fall of 1919. Reduced to about half their original form, they were read before the Columbus meeting of the American Institute of Mining and Metallurgical Engineers, October, 1920, and will so appear in vol. 64 of its *Proceedings*. They are now given in full, together with some recent additions which are indicated by enclosure within square brackets [].

[1] *J. Am. Chem. Soc.*, vol. 41, p. 1010 (1919).

and stannic hydrosols) consist of or contain groups of molecules arranged in an unoriented, haphazard or random manner; so that even if the molecules themselves are crystal prototypes, they can and do occur in non-crystalline groups.

Zay Jefferies[3] has shown that with metals, in general, the cohesion of the amorphous phase equals that of the crystalline phase at the lowest recrystallization temperature, which he terms therefore the equicohesive temperature; and based on this he has explained the mechanical behavior of metals at various temperatures. At higher temperatures than the equicohesive point, the cohesion of the amorphous phase decreases more rapidly than that of the crystalline phase—i.e., it becomes relatively softer—whereas at lower temperatures than the equicohesive point its cohesion is greater and increases with much greater rapidity than that of the crystalline phase. Fig. 1, taken from Jeffries' paper, shows these facts diagrammatically.

These differences between the two phases are intelligible from the following considerations: The atoms in the crystalline phase, though arranged in regular layers, are on the average closer packed,[4] and therefore at lower temperatures cannot draw together as much as those of the amorphous phase, which consequently becomes relatively stronger at lower temperatures; whereas at higher temperatures, the molecules of the amorphous phase become separated and mobile more readily than those of the crystalline phase, for they possess initially more potential energy[5] since they are less closely packed—i.e., further apart on the average—and are, therefore, less strongly held to one another by molecular forces; consequently the amorphous phase becomes relatively weaker at higher temperatures. The fact that, even at room temperatures, some of the molecules of some metals possess mobility was demonstrated by Roberts-Austen, who showed that gold and lead when placed in contact diffused into each other after a lapse of years.

Recrystallization

As a result of this preferential softening, the amorphous or colloidal phase, at relatively higher temperatures, acts like a very viscous solvent surrounding and nourishing the more rigid crystals; and as increasing temperature renders this solvent less viscous, the metal strives toward crystallinity, which represents the position of minimum mechanical potential. Some metals, like lead, undergo such molecular readjustment, even at room tempartures. During this process of recrystallization below the melting point it has been observed that, in general, large crystals tend to grow at the expense of the small ones. A similar process is observable in the crystallization of salts, for, as Hulett has shown, finely ground powders are more soluble than a coarse grinding of the same substance. Therefore the smaller metal crystals would preferentially dissolve in the "amorphous" or colloidal phase. Bearing in mind that the growth of a crystal means that there are deposited upon it more molecules or molecular groups (crystallogens) than are dissolved off, the larger masses would naturally get most of these extruded units, just as happens in the cosmic field. The larger crystals have the advantage of exposing to the solvent action of the amorphous or colloidal phase less surface per unit of mass; and when metal molecules or molecular groups deposit on a crystal, they release a certain amount of energy, the heat of crystallization or latent heat of fusion, which helps to make the amorphous or colloidal phase more fluid.

Do the small crystals dissolve molecule by molecule, or in molecular masses or groups as well? It would seem that in some cases at least molecular groups are dissolved off and transported, for in strained metals especially recrystallization is extremely rapid. Thus in sheet aluminum[6], when heated to a suitable temperature, recrystallization takes place like a flash, the originally smooth sheet becoming coarsely granular, suddenly, before one's eyes. The writer has observed[7] ultramicroscopic particles streaming from a crystal of sodium citrate as it went into solution, indicating that initially solution took place, at least partially, in colloidal molecular masses.

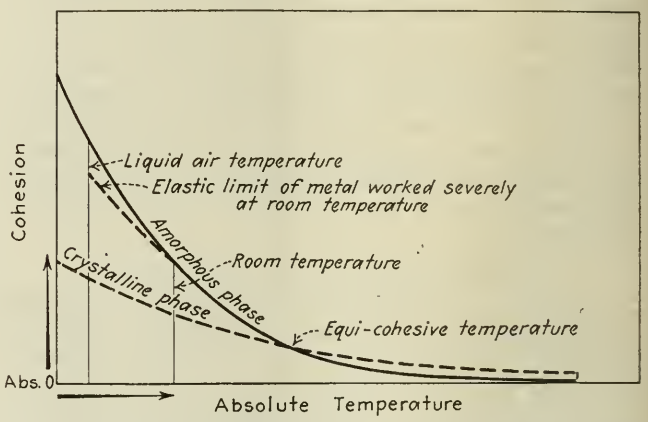

FIG. 1. DIAGRAMS SHOWING CHANGE IN ELASTIC LIMIT AND HENCE DUCTILITY OF A METAL SEVERELY WORKED AT A CERTAIN TEMPERATURE AND TESTED AT AND BELOW THAT TEMPERATURE

The amorphous or colloidal phase becomes, therefore, a medium for the transfer of atoms, molecules or molecular groups from the small to the larger crystals, and also tends to annihilate itself by allowing its constituent oriented and unoriented particles to be incorporated into the huge Juggernaut crystals.

The preceding remarks have been based upon a consideration of *pure* metals, which are practically never met with, for most commercially pure metals contain as impurities several other metals, elements or compounds. Besides, most metals are used in the form of mixtures or alloys—steel, brass, bronze, type-metal, babbitt metal, solder, etc. The introduction into a metal of a single impurity, even in minute percentage, usually produces a very marked change in its properties or behavior—for example, 1 part of carbon in 10,000 of iron, or 1 part of copper in 10,000 of gold—and as it seems to me that in many cases this effect involves, at some stage, the direction, modification or inhibition of the normal crystallization of the metal by a colloidal dispersion of some substance or substances, it is desirable at this point to consider the general question of the effect of colloids upon crystallization.

Most experiments in this field have been made with aqueous solutions or dispersions, and the rule seems to

[7] Alexander and Bullowa, "Archives of Pediatrics" (1910).

be that a colloid which is adsorbed by, or which forms an adsorption compound with, the initial colloidal aggregations of the crystallizing substances either prevents the growth of its crystals or groups beyond colloidal dimensions or else forces their growth to assume globulitic or dendritic forms which vary with each substance, each colloid and each set of conditions. Thus gelatin, gum arabic and similar stabilizing or protective colloids, even in small quantity,[8] oppose the aggregation of the gold atoms at the instant of their liberation to such an extent as to yield a highly dispersed hydrosol under conditions that would otherwise yield a coarse blue or black gold suspension. The use of gelatin (about ½ per cent), eggs and similar colloids in ice cream[9] leads to the production and stabilization of very fine or colloidal ice particles, giving the product the desired smooth velvety texture; without colloids the ice cream becomes grainy or sandy, the undesirable roughness being due to large or spicular crystals.

Coming now to substances which form solid crystals at ordinary temperatures, we see in Table I that colloids exert a powerful inhibitory action on the crystallization of plaster of paris,[10] not only preventing the formation of ordinary crystals but delaying or even entirely preventing the "setting."

TABLE I. EFFECT OF GELATIN ON PLASTER OF PARIS

1 Part Plaster to 1 Part Water Containing Gelatin per Cent	Time to Set in Minutes	Microscopic Appearance of Slide
0	40	Characteristic crystals of calcium sulphate.
1/100	50	No crystals, except in a few spots where some colloid-free solution had diffused out.
1/10	260	No crystals.*
1/4	510	No crystals.*
1/2	960	No crystals.*
1	Not set in 48 hr.	No crystals.*
2	Not set in 48 hr.	No crystals.*

*No regular, ordinary crystals, the mass consisting of aborted, modified or sphero-crystals, or of colloidal crystals or other minute unoriented groups, or of a mixture of these.

The effect of colloids on the crystallization of ordinary salts is most remarkable[11] and I hope to be able to publish further results of experiments along this line. Meanwhile I may say that with each salt, each colloid and each set of conditions (concentration, temperature and pressure) there are formed characteristic groupings in which dendrites and spherulites are exceedingly common; also very beautiful and complicated leaf-like, branching and cellular forms, reminding one forcibly of living structures. Indeed it seems evident that the growth and shape of living organisms are largely controlled by the complex interplay of the forces of crystalline growth, as restrained, modified and directed by colloidal substances.

If the amount of colloid is so small that it is all adsorbed by these structures before the salt has entirely crystallized, well-defined crystals of the colloid-free salt may appear. On the other hand, if enough of the colloid is present, ordinary visible crystallization may be entirely prevented; and in intermediate cases abortive attempts at crystallization register themselves in curious formations. The preparation of a few microscopic slides with solutions of NaCl, $MgSO_4$, Na_2So_4 and Na_2CO_3, containing from 0.5 to 50 per cent (figured on the dry salt) of gum arabic or gelatin, will give some idea of these effects[12] and show their striking resemblance to the microstructure of metals. The slides may be made by putting on a drop of the mixture and allowing it to dry without a cover glass. During the drying, changes in temperature and concentration occur within the drop, with the result that the field changes progressively from the center.

Production of Fine Grain

This resemblance led me to comment[13] as follows regarding metals: "Since coarsely crystalline metals are brittle, tending to split along the lines of crystal cleavage, various physical and chemical means are employed in technical practice to obtain a hard, fine-grained structure.[14] Among the physical methods are chilling and rolling, while the chemical methods involve the removal of undesirable constituents (as in the conversion of pig iron into steel), or the addition of desirable constituents (as in case-hardening and the manufacturing of 'chromium steel' and 'nickel steel'). For example, P. Pütz[15] has shown that the predominant effect of vanadium in steel is to decrease the size of the ferrite grains and make the material harder; it renders the ordinary structure due to pearlite fine-grained and homogeneous.[16]

"Now while the question is one of very great complexity, many of the facts at present available seem to indicate that one of the causes favoring the fine-grained structure is the inhibition of crystallization by substances colloidally dissolved in the molten mass. Thus, part of the carbon in iron and steel exists in the graphitic form, and as graphite is slightly soluble in iron[17] some of it will, under proper conditions, be found in colloidal form.[18] Besides, metals may dissolve one another and other substances colloidally, but in the case of ordinary metals this is not easy to demonstrate, although a differential solvent acting in the presence of a protective colloid might leave a colloidal residue."

Amorphous Metal and Cold Work

In conclusion let us consider some of the aspects of the amorphous theory regarding the change of metals under strain, which is stated by one of its principal advocates, Rosenhain, as follows[19]:

"It may be well to state precisely what is understood, in this connection, by the term 'amorphous.' In accordance with Beilby's views and their recent development by the author [Rosenhain] and his collaborators,[20] the amorphous condition is one in which the crystalline arrangement of the molecules is completely broken up, so that the molecules remain in a state of irregular arrangement similar to that which is supposed to exist in the liquid state. In fact, the amorphous phase is re-

[8] Excessively minute quantities may have the contrary effect and actually sensitize. While this condition has not been observed in metals, it evidently forms the basis of the phenomenon known to physicians as anaphylaxis.

garded as being—from the point of view of the phase doctrine—identical with the liquid phase. Now extremely undercooled liquids are well known in such substances as glass, vitreous silica, etc., and they are hard, brittle bodies devoid of plasticity and of crystalline structure. Amorphous metal is, therefore, to be regarded as being identical in nature with the liquid metal if that could be cooled down to the ordinary temperature without undergoing crystallization. It is admitted that such extreme undercooling of metals has never been actually accomplished, and objections to the whole concept of amorphous metal have been based on that ground. These cannot be discussed here, but they have been fully dealt with by the author [Rosenhain] elsewhere.[21] At the present moment it may well be claimed that the theory of an amorphous phase in metals, produced as a result of mechanical disruption of the crystalline arrangement of the molecules, holds the field as the best working hypothesis available. There are admittedly outstanding difficulties, but these the author regards as being inevitable in a theory whose wide generalizations cover a field which has as yet been but partially explored.[22]

Effect of Plastic Deformation

"The general effect of slowly applied or 'static' plastic deformation may be summarized as follows: The metal in the cast or the annealed state is an aggregate of crystals; when the metal undergoes plastic deformation, the crystals are deformed in the same general sense as the mass of metal. This change of shape of the crystals is accomplished by a process of slip or gliding by which layers of the crystal slide over one another along certain gliding planes. Such slip occurs on a great multitude of planes in each direction and, as a rule, it must occur on at least three sets of planes, but it may occur on a greater number. This slip is accompanied by a certain disturbance of the crystalline arrangement of the molecules on or near the surfaces of the slip. If the deformation has been slight, the disturbed molecules may be able to rearrange themselves in accordance with the crystalline system by which they are surrounded, and the completely crystalline character of the metal will then be unaffected by the deformation. When the deformation is severe and if it is intensely localized, as when a single crystal is bent upon itself, the molecular disturbances at the slip surfaces become larger and permanent layers of amorphous metal are formed on each surface where slip has occurred. Ultimately the metal, as a result of extreme deformation, becomes a mass of crystal fragments embedded in relatively thick layers of amorphous material. This change is accompanied by an increase in the hardness of the metal and —in the majority of metals—by a measurable decrease in density."

This amorphous view stresses particularly the entire absence of regular orientation or crystallization in the so-called amorphous phase, whose molecules are supposed to be in the random and, mainly, isolated state assumed to exist in liquids. I believe, however, that the amorphous phase consists largely, if not entirely, of molecular groups, many of which may be oriented in the form of ultramicroscopic crystals or crystal fragments; and that its properties are due, not to the entire lack of ori entation among its particles, but rather to the fact tha many or the majority of its molecular groups are of col loidal dimensions. Since in metals the molecules are very close together and possess extremely high cohesion o crystallization tendency, it does not seem possible tha the amorphous phase can be composed entirely of isolate molecules, or even entirely of non-crystalline groups With gold hydrosols where the dispersing water exer cises a restraining influence, the X-ray spectroscop shows that the ultramicroscopic, and even that th amicroscopic, gold particles are crystalline. With th most drastically chilled metal, allowing for the high vis cosity and its rapid increase, it does not appear conceiv able that no tiny ultramicroscopic crystals form, or a least that there is no grouping, regular or irregular of the metal molecules. The facts indicate and are i harmony with the conception of amorphous metal as a isocolloid—that is, as a dispersion of colloid crystals crystal fragments or non-crystalline groups in still mor finely dispersed metal—or else a mixture of colloida crystalline and non-crystalline groups, forming a soli gell-like mass. The fineness of its particles and th enormous development of free surface found in all col loids are its critical factors.

The idea here advanced, that metals, in the course o their aggregation, pass through a colloidal stage whic exerts a powerful influence on their structure and prop erties and may even be partly retained in the final prod uct by "protection," adsorption, crystallization or in crease in viscosity due to quenching, is not limited to th field of metallurgy, but may be applied to any substanc or system where a portion or a component becomes col loidal while the remaining portion or components ar outside of the colloidal zone. The case of glass ha been mentioned in the first article of this series, wher some components apparently inhibit the ordinary crys tallization of the others under operating conditions This theory may also account for the fact that under on set of conditions Na_2CO_3 crystallizes with ten molecule of water, while under other conditions it may be crys tallized with seven molecules of water; and the effloresce crystals hold only one molecule of water. Sodium sul phate acts similarly, forming $Na_2SO_4.10H_2O$, $Na_2SO_4.7H_2O$ and the anhydrous salt Na_2SO_4.

Influence of Atomic Groups

Liquids appear to consist largely of atomic or molecu lar groups and solids of still more complex groups, th size and nature of which depend upon conditions[23]; an among these groups those of colloidal dimensions as a rule appear and must then be reckoned with. Th "twinning" of crystals,[24] which is a marked characteristi of γ iron, α brass, and especially of worked or strained metals on annealing, is probably due to colloida influences.

This and many other questions, such as the effect o other metals on iron and steel (so-called alloy steels) and the adsorption of gases at the free metallic inter faces, etc., though germane to this paper, must be lef

[21] Rosenhain, *Engineering*, October, 1913. *Internat. Zeit. Metallographic*, vol. 5, 1914.

[23] W. E. S. Turner ("Molecular Association," p. 99) says: "The formula of a substance shall be recognized as a function of the physical conditions under which it exists, so that the formula for elements is X_n, for compounds $(XY)_n$, where n is to be specified according to the conditions. Although we are far from realizing how n varies for most substances, the adoption of such formula would bring home clearly the fact that both the physical and the chemical behavior of a substance may be closely dependent on the value of n."

[24] [See paper by P. Niggli, *Koll. Zeit.*, vol. 10, p. 268, entitled "Colloid Chemistry and Twin Crystals."]

for future consideration. The work of P. W. Bridgman[25] with high pressure is very suggestive. For example, he found that, whereas cylinders of soft tool steel (1.25 per cent C) and soft chromium-nickel steel (Krupp Special E.C. 60.0) ruptured under the same pressures, whether water or mercury was the pressure-carrying fluid in contact with the metal, the same steels when hardened broke at much lower pressures (about one-third) with mercury than with water. The rupture was due to the amalgamation of the steel, which when once started spreads rapidly under the high hydrostatic pressure.

But even a pressure of 6,500 atmospheres for 12 hours failed to cause the amalgamation of hard or soft steel rods, although the rods were polished with fine emery paper immediately before being plunged into the mercury. On the other hand, hard and soft steels and cast iron (also Al, Ni and Co) were promptly amalgamated on the fresh surfaces formed by breaking the metals under mercury.

Bridgman speaks of "dirt" preventing amalgamation; but from the recent work of W. B. Hardy, on fresh surfaces, and of I. Langmuir and others, on adsorption, it would seem that instantaneous adsorption from the atmosphere, probably of gases, is responsible, although a change in the nature of the surface may have some effect also. Freshly cleaved sheets of mica show a similar effect; their initial coherence is speedily lost. With steel, as with gelatin jellies, the quickly chilled specimens show greater porosity because of the greater total area of the diffusion paths consequent upon finer subdivision.

(Part III, dealing with White Metal and Brass, will appear in a subsequent issue.)

Need for a Scientific System for the Evaluation of Gelatin and Glue

DR. R. H. BOGUE, of the Mellon Institute of Industrial Research, speaking before the New York Section of the American Chemical Society on Jan. 6, stressed the very evident need for a better and more logical system for determining the value of gelatin and glue. Evaluation methods, which have been used in the past and are still adhered to, do not adequately differentiate these products. There are three fundamental reasons for this.

Three Faults of Present System

First, the methods of grading do not at present invariably get at the real property or properties which mean value. They are usually aimed in the right direction, but too often fail in attaining the end desired. A gelatin or glue costing 50c. may, by the present system, be judged inferior in gelatin content or in sticking qualities to one costing 45c. This is not the fault of the manufacturer or the jobber, but is rather a reflection on the chemist for not providing the former with a truly representative system for evaluating his product.

Second, there are so many systems now in use for designating quality—in fact, nearly every glue house in the country uses somewhat different methods—that it becomes almost hopeless to attempt to specify a desired product by any symbol and be certain that a product of the desired properties will be obtained. The same specifications sent to a number of glue houses will not result in the selection by them of exactly equivalent lots, and the several lots obtained will not be equivalent in binding strength or in gelatin content. The standards for reference are inadequate. A viscosity of 45 in one house may be the equivalent to a viscosity of 100 in another house due to the employment of different instruments, or different temperatures, or different concentrations.

Third, an inevitable consequence of this system, and which reacts to the advantage of the manufacturer, is the confusion of the consumer. It leaves too wide a margin upon which the unscrupulous salesman may play. There being no standard of quality, there can be no standard of price that is sufficiently conspicuous to the consumer to make impossible the "putting over" on him of questionable deals.

It should be possible to establish specifications in gelatin and glue that are comprehensive and intelligible, and every such effort should be given careful consideration. From among the many suggestions, a competent committee of chemists should select one, or some combination, that shall be established as a standard.

Proposes Viscosity as Basis for Primary Evaluation

Dr. Bogue has studied the fundamental relations between gelatin content and adhesive strength on the one hand, and jelly strength, viscosity and melting point on the other hand. He has found that a differentiation by noting the melting points is also expressive of the differentiation in the gelatin content and the adhesive strength. The gelatin content is a fundamental property and the adhesive strength is the most important practical property of glues. Since these are not easily determined, but are found to be proportional to the melting point, the latter is a satisfactory test upon which to base grade.

But the melting point test is tedious and not well adapted to control work in a large plant. It was found that the viscosity at a temperature of 32 deg. C. and a concentration of 20 per cent made by the MacMichael viscosimeter differentiated gelatins and glues in the same order as the melting point, and was especially well adapted to plant control work. The instrument is a standard one and obtainable from any chemical supply house; its readings may be expressed, without any calculation, in absolute degrees or centipoises. Thus we have a specification in a universal language, upon a standard instrument, that is representative of actual quality, and that is readily adaptable to plant practice. This, according to Bogue, should constitute the primary basis for evaluation.

Secondary tests, also expressed in some standard language, may be made to determine the adaptability of the product to a given service. These include the customary tests for foam, grease, reaction, etc. A test for hydrogen-ion concentration should be added, as the properties of the product vary with this factor.

The designation of grade may well be expressed in terms of the viscosity in centipoises (or more conveniently in centipoises divided by ten) of the material as shown in the test outlined above. This number could be used as a subscript to a letter referring to the origin of the material. Thus products designated as H_{13} and B_{16} would refer respectively to a material from hide having a viscosity lying between 130 and 139 centipoises and to a material from bone having a viscosity between 160 and 169 centipoises.

The Bucher Process for the Fixation of Nitrogen*

An Account of Small- and Large-Scale Experiments in the Production of Sodium Cyanide From Soda Ash, Carbon and Iron—Comparison of Results With Those of Other Investigators—Details of Furnace Design

By M. deKAY THOMPSON

THE fixation of nitrogen by means of the reaction $NA_2CO_3 + 4C + N_2 = 2NaCN + 3CO - 138{,}500$ calories in the presence of iron as catalyzer and at a temperature of about 1,000 deg. C. was discovered by Lewis Thompson in 1839, but on account of the extensive research carried out by Prof. John E. Bucher[1] in recent years on this reaction it is commonly known as the Bucher process.

During the war a plant was built by the government at Saltville for the purpose of making cyanide by this reaction.[2] The briquetted mixture of soda ash, carbon and iron was heated in ferrochromium tubes 9 in. in diameter by means of gas, and the charge was passed continuously through these pipes. The plant was not running at full capacity at any time and was shut down when the armistice was declared. As far as is known, there is at present no plant operating commercially according to this process. Besides the article by Bucher referred to above, shortly after the present work was begun there appeared an article by Ferguson and Manning[3] in which it was shown that the reaction is reversible and the quantity of cyanide formed depends on the amount of carbon monoxide in the nitrogen-carbon monoxide mixture in contact with the solid substances of this reaction. Bucher states in his paper that just as good results are obtained with air which has been passed over hot carbon as with pure nitrogen. This statement is evidently incorrect. It was also found that for a given percentage of carbon monoxide in the gas a higher cyanide yield was obtained at 1,000 deg. C. than at 940 deg., which is of course a necessary consequence of the fact that heat is absorbed in the formation of cyanide. Two other articles on the Bucher process may be mentioned. Posnjak and Merwin[4] find some nitrogen compound other than sodium cyanide in the crude technical product, and confirm Bucher's reaction given above. Morimoto[5] easily obtains yields of 75 per cent, using iron turnings and charcoal at 820 to 950 deg. C.

It was found necessary in the course of this work to do a considerable number of experiments on a small scale on account of the unsatisfactory yields of cyanide obtained in the first experiments when the mixture was made from metallurgical coke and iron flour. These were supposed at the time to be the proper materials. Furthermore, the briquets in many cases became very soft or fell to powder on the treatment with nitrogen, and it was necessary to find some way of preventing this disintegration. These experiments will be described first.

Procedure in Small-Scale Experiments

The briquetting was carried out in a meat chopper as described by Bucher after mixing hot in a Werner & Pfleiderer mixer and the briquets were dried in covered iron pots, heated by a bunsen burner. A few experiments were made with briquets of $\frac{3}{16}$ in. diameter, the majority with briquets of $\frac{5}{16}$ in. diameter, but the diameter was not found to have any effect on the result. The heating in nitrogen was done in vertical tubes. In the preliminary experiments a steel tube of 1.25 in. inside diameter and 2 ft. in length was heated by a resistance coil which was insulated from the tube by a sheet of asbestos, and also heat-insulated on the outside. In later experiments iron pipes of $1\frac{3}{8}$ in. inside diameter, $1\frac{11}{16}$ in. outside diameter and 5.5 ft. long were used, holding about 600 g. of briquets. These were heated by passing an alternating current through the pipe. The lowest voltage available was 10 volts, which gave 2,400 amp. when the pipe was cold and 1,600 amp. when hot. The temperature was regulated by opening and closing the circuit at short intervals approximately of 1 minute duration. This was equivalent to a continuous input of about 2 kw.

These pipes were heat-insulated with asbestos pipe covering somewhat too large to fit the pipe, and the space between the pipe and the covering was filled with loose asbestos-magnesia mixture. The temperature of the outside of the pipe was taken at regular intervals at five points along the tube by a platinum-platinum rhodium thermoelectric couple protected by silica tubes. These tubes were inserted through the asbestos pipe covering and carried in direct contact with the iron tube. Repeated comparisons between the indications of the couple and of an optical pyrometer showed that the couple read about 80 deg. lower than the temperature of the pipe. All readings were corrected accordingly. The temperature of the briquets inside the iron tube may have been a few degrees below the temperature of the tube itself, but no comparison was made. The briquets were held up by an iron gauze placed inside the tube. The nitrogen was taken from a tank of highest grade nitrogen, and was measured by an ordinary house dry gas meter. The tube was filled with briquets through that portion of its length which was heat insulated, then with nitrogen, and the current applied. The exit gas was lighted, and when the flame would no longer burn (in later experiments analyses for carbon monoxide were made until the absence of the gas showed the reaction was complete) the pipe covering was removed, and the tube permitted to cool

*This research was carried out for the U. S. Smelting, Refining & Mining Co. The author wishes to express his thanks to this company for permission to publish these results.

with a small current of nitrogen passing through it. The charge was removed when cool, divided into a top, middle, bottom and average portion, ground, and analyzed for cyanide by titrating with nickel sulphate,[4] and for total alkali by titrating with sulphuric acid, using methyl orange as indicator.

The temperature of the pipe was usually between 940 and 1,040 deg. C. In some pipes there was excessive local heating, and in this case the pipe was rejected.

It may now be interesting to compare some of Bucher's results with those obtained in these experiments.

Comparison With Bucher's Results

In Bucher's experiments, No. 5, made with graphite, iron and sodium carbonate, the flame was colorless, while in No. 4, where the iron was omitted, the flame was yellow colored. Bucher takes this as evidence "showing that no sodium was formed when iron was present." In the present experiments, where iron was always present, the cool top of the tube frequently had an incrustation which contained metallic sodium. On throwing it into water it reacted violently and sometimes took fire. At the same time the flame was colorless, consequently a colorless flame is no evidence that small amounts of sodium are not produced at the same time that cyanide is formed.

TABLE I. EFFECT OF GRINDING PETROLEUM COKE AND IRON

(Iron flour contained 91 per cent iron. Analysis of dried briquets: 21.3 per cent iron, 29.5 per cent soda ash. Duration of each experiment: one hour.)

No.	Hours Grinding	Deg. C.	Per Cent of Cyanide	Average Conversion in per Cent
15	11	950–1,050	2.7	20.5
16	57	950–1,050	12.2	47.0
17	72	950–1,050	16.0	61.5
18	15	950–1,050	7.0	41.5
19	23	1,050	12.0	53.6
20	30	1,050	7.4	51.0
21	30	1,050	8.7	*49.2
22	70	1,050	8.4	39.0

* Duplicate of No. 20.

Bucher does not discuss the question as to what composition produces a hard briquet after treating with nitrogen. In the present experiments it was found that the briquets increased in hardness when the content in alkali and iron was increased at the expense of the carbon. Briquets which after heating analyzed about 80 per cent iron plus total alkali (with the iron and alkali in about equal amounts) were hard, while if this sum was only 70 per cent, the briquets were nearly always soft. This would correspond to about 24 per cent iron as Fe_2O_3 and 29 per cent soda ash in the dried briquets before the run.

The percentage of sodium converted to cyanide is one of the most important factors in this process. The results obtained on this point may be stated in a very few words: (1) The finer the particles of iron and carbon the higher the conversion of the sodium to cyanide (or the "purity," as Bucher calls it), and (2) the highest results were obtained with those forms of carbon that had very little ash, such as petroleum coke, lampblack, graphite, gas carbon and charcoal. Coke with 10 per cent ash gave very poor results, as shown below. The effects of prolonged grinding in a ball mill are shown in Table I.

These results are apparently contradictory, for in Nos. 15 to 17 there is a continued increase in conversion with the duration of the grinding, while in Nos. 18 to 22 the conversion first increases and then decreases. The only difference in the procedure in the two series was that in the first a small ball mill of about 2 liters total capacity was used, in the second a large one about 2 ft. in diameter. Steel balls were used in both mills. This question was not pursued further, for better results were obtained without excessive milling.

The conversion in these runs was decidedly low, and it was evident no better could be obtained with this iron.

Experiments With Different Forms of Iron

The experiments tabulated in Table II show the effect of using different kinds of iron, including precipitated iron oxide, which is the finest form obtainable. The iron oxide was prepared by dissolving iron sulphate and precipitating this with a solution of soda ash. The precipitate was washed free from sulphate, dried and ground a few hours with carbon in a ball mill. Soda ash was then added and the grinding continued half an hour.

The important result of small-scale experiments was that the best conversion with iron flour was about 60 per cent, with iron scale as high as 76 per cent was obtained, both at the expense of very long milling, and with precipitated iron oxide (which was of course reduced to finely divided iron in the furnace) 90 per cent conversion was reached. Coke containing 10 per cent ash gave low conversion (No. 32).

Before it was found that mechanically strong briquets could be made without a binder, sodium aluminate (No. 28) and anthracite ashes (No. 29) were tried as binders. The ashes had very little binding quality, and both were harmful. Gas carbon (No. 54), graphite (No. 71) and charcoal (No. 73) were all tried and gave excellent results when used with precipitated iron oxide. A final lot of briquets made from charcoal for the purpose of testing the product for leaching purposes gave the following analysis: Sodium cyanide 34.5 per cent, conversion 92.5 per cent, iron 41.9 per cent. These briquets were more than sufficiently hard.

TABLE II. EXPERIMENTS WITH DIFFERENT FORMS OF IRON

In heating a mass of properly prepared briquets for

[4] Lundell and Bridgman, *J. Ind. Eng. Chem.*, vol. 6, p. 554 (1914).

the purpose of producing cyanide, it is essential to have a temperature between 900 and 1,500 deg. C. throughout the whole mass. Too low a temperature to produce cyanide may still be high enough to cause a continuous evolution of carbon monoxide from the action of carbon dioxide dissociated from the soda ash on the carbon of the briquets. This will prevent getting good results. The lining of the furnace must be neutral or basic so as not to be attacked by the charge, and must not contain any oxides reducible under the furnace conditions, otherwise there would be carbon monoxide from this source.

These briquets are not good enough conductors of electricity to heat from a cold state by applying any reasonable voltage, and in order to accomplish this result it was planned to mix them with gas carbon passed through rolls $\frac{1}{32}$ in. apart and sifted free from the powder. The granules of gas carbon were of small size so that they could be separated from the briquets by sifting after treatment with nitrogen. It was found subsequently that a similar plan had been patented by Shoeld,[7] the only difference being that in this patent the conducting material is about the same size as the nonconducting material mixed with it.

Design of Furnace

A furnace was designed and built according to Fig. 1. It consisted in cylindrical iron shell divided into two halves by a plane passing through its axis. The edges were flanged so the two halves could be bolted together. It was supported on trunnions with a worm and gear attachment for dumping the charge. The first lining consisted of magnesite bricks, which were built into the two halves separately. The temperature inside could be taken by inserting a thermoelectric couple into any of three steel tubes running through the furnace perpendicular to the axis, at the top, at the bottom and at the center.

It is evident from considerations of heat flow that in order to get a fairly uniform temperature through a section of the furnace perpendicular to the axis of the cylinder it would be necessary to have a lining with a much lower heat conductivity than that of the charge. The first experiment showed that the magnesite brick lining did not meet this requirement, for it was found that the temperature of the charge next the walls was only 600 deg. while that at the center was 1,000 deg. It was also found that with one or two exceptions the temperature at the bottom was much less than at the top. The cause of this was unquestionably the lower resistance of the lower part of the charge due to the pressure of that resting on it. In a continuous furnace where the charge would pass through both the hot and the cool parts, this second difficulty would disappear, but where a lot of briquets are heated and then dumped, either of these faults would prevent the efficient formation of cyanide. The results of some of the runs in the large furnace with magnesite brick lining are given in Table III.

[7] U. S. Pat. 1,317,327 (Sept. 30, 1919).

Discussion of Results

This table shows that some cyanide was made when a fairly uniform temperature was reached by means of a layer of gas carbon placed as an annular layer between the charge and the lining. (See experiments 58, 61 and 62.) The heat was generated in this layer; and at first the outer layer of briquets was hotter than the center. Later, when the briquets began to conduct, the center became somewhat warmer than the outer layer of briquets. The experiments were made merely to see what could be done with the furnace as it stood; it

would evidently not be possible to operate in this way for production purposes.

In experiment 62 the bottom happened to be hotter than any other part of the furnace. This must have been due to some unevenness in the charging; perhaps there was a smaller proportion of gas carbon at the bottom than elsewhere.

These experiments showed that a better heat insulation in the furnace walls would be necessary. The magnesia inner lining should be retained on account of its basic properties, but a thin layer of this should be surrounded with the best heat insulator obtainable. Unfortunately a magnesia pipe of the proper size could not be obtained. An ordinary fireclay pipe was tried surrounded with a special infusorial earth. It was found that this material was not perfectly dry and when used as a lining moisture continued to come off for hours. In order to save time it was then thoroughly dried in a reverberatory furnace, and tried again with only gas carbon as a charge. The reverberatory furnace had eliminated the moisture, and there was very good temperature distribution from the center to the clay pipe, but the exit gas still showed the presence of carbon monoxide. In order to get a high enough temperature at the bottom, the resistance was increased by placing inverted Denver crucibles in piles of two or three deep on the bottom electrode. These, as well as the clay pipe lining were badly attacked by the carbon, giving the evolution of carbon monoxide mentioned. The crucibles produced the result desired, of bringing up the temperature of the bottom part of the furnace. It was found that if the furnace were tilted in a horizontal position, the bottom heated up as much as the top without the crucibles. (Experiment 96.)

The results of the experiments with this furnace show (1) that if used the "batch" method the furnace would have to be tilted on its side to get a uniform temperature throughout its length, and (2) that a lining with at least as low a thermal conductivity as infusional earth must be used for a furnace of this diameter (8 in.), and of still lower for a larger diameter.

Suggested Alterations in Furnace Design

A continuous furnace might be made by imbedding two carbon electrodes in the walls of the furnace as in Fig. 2, where the feeding and discharge mechanism are left out. It is probable that there would be no difficulty on the score of different temperatures at the top and bottom, for the entire charge would pass the hottest part.

It is also possible that after warming up the furnace, cold briquets fed in at the top would be sufficiently warmed by the time they reached the electric circuit to be conducting, without the admixture of gas carbon. This would reqquire less power and avoid sifting. These were points, however, which would require extensive alterations in the furnace to verify.

It seems that simply enlarging the scale of the experiments with iron pipes has a great deal to recommend it. If steel tubes of the right dimensions were well lagged and protected from the action of the air, connected in series with a transformer, and each tube connected with a hopper and a discharge arrangement, it is not easy to see where any difficulty would come in operating.

It would be well worth while trying either or both of these furnaces on a full-size scale.

The following table gives the results of the calculation of power required per pound of cyanide.

Power required—	Kw.-Hr.
For the reaction	0.75
To raise 5 lb. of briquets to 900 deg. C.	0.60
Radiation loss (assumed the same per pound of cyanide as in the large experimental furnace, the charge requiring three hours to pass)	0.65
For heating nitrogen	0.10
Total	2.10

Cost, at 0.5c. per kw.-hr. = 1.1c.

If an equal amount of granular carbon had to be added this would require an additional 0.86 kw.-hr. Assuming that 35 tons of briquets are to be treated a day, producing 7 tons of cyanide, and that each tube could deliver 7 charges a day, 600 ft. of 8-in. pipe would have the required capacity. A cubic foot of briquets weighs about 50 lb. Assuming these pipes to be made of the same kind of iron as the pipes used in these experiments and the walls 1 cm. thick, the resistance of the 600 ft. would be 0.047 ohm when hot. This would correspond to a current of 5,100 amp. at 240 volts.

The cost of raw materials per pound of sodium cyanide would be approximately as follows:

	Theoretical, Lb.	Actual, Lb.	Cost, Cents
Soda ash	1.1	1.5	4.1
Carbon	0.5	0.6	0.75
Cu.ft. nitrogen	3.6	11.0	0.2
Total cost of raw materials			5.
Cost of power			1.1
Cost of power and materials			6.1

It is possible that the total cost would be not less than twice this, or 12c. a pound.

Glass Industry Expanding in Australia

Three glass-manufacturing companies have been registered in Melbourne recently. These are the Victorian Glass Bottle Works Proprietary, Ltd., South Yarra, authorized capital £5,000; the Crystal Glass Manufacturing Co., of Western Australia, Ltd., authorized capital £50,000; and the Zetland Glass Bottle Works, Ltd., authorized capital £150,000.

Electrolytic Iron a Commercial Product*

Manufacture of Boiler Tubes of Electrolytic Iron at Grenoble, France—Briquetted Forms of Pulverized Electrolytic Iron Made Into Magnet Cores at Hawthorne, Ill.—Remarks on Leaching Iron From Sulphide Ores With Subsequent Electrolysis

BY BRADLEY STOUGHTON
Consulting Metallurgical Engineer, New York City

FOR more than 50 years attempts have been made to produce pure iron on an industrial scale by means of electrolysis, which modern metallurgy recognizes as the "tonnage production" method for metals in a pure form and which is the established process since a number of years for pure copper, gold, silver, aluminum, lead, zinc, etc. The combination of unexcelled cheapness with unexcelled utility for many purposes, possessed by *impure* iron, has diverted attention from the superior utility of the *pure* metal over pure copper, aluminum, etc., at a fraction of the price. We now know that pure iron is at least as soft and has better cold-working or drawing qualities than either pure copper or aluminum, besides having great advantages for household and machine purposes in respect of price, durability, maintenance of a bright surface, resistance to corrosion or tarnishing, to heat, etc.

Process of the Société "Le Fer"

The Société "Le Fer," which numbers among its directors the eminent metallurgist Dr. Léon Guillet, controls the patents of Anthèlme Boucher, which were under laboratory investigation for several years prior to 1915, when the first industrial installation was made at the iron and boiler works of MM. Bouchayer and Viallet at Grenoble, France, using electricity from hydro-electric plants in the Swiss Alps.[1]

The electrolyte is ferrous chloride; the anode is iron in the form of cast iron; the cathode is a revolving mandrel upon which the pure iron (containing about 99.97 per cent Fe) is deposited in the form of a tube, which is annealed to eliminate the embrittling hydrogen, stripped and used as a boiler tube, either with or without drawing through a die.

The metal is so soft that no inner "ball" is used in the drawing operation. The 0.03 per cent of impurity is made up of the metalloids of the cast iron—namely, traces of carbon, silicon, sulphur and phosphorus. Hydrogen, which deposits with the metal, is completely eliminated by heat, as indicated by chemical analysis and physical properties, which will be described later. From the commercial viewpoint the Boucher process gains by avoiding the following operations in the making of a boiler tube: Purifying the pig iron; rolling and piercing the billet; annealing and roughshaping the tube. The costly items are as follows: Cast iron for anodes;[2] loss of about 20 per cent in slimes due to the use of a soluble anode; and the use of electricity, which amounts to about one-quarter to one-third of a horsepower-year per ton of tubes produced.

In the matter of purity the Boucher tubes excel any other industrial product, and the process has the great advantage that a thin tube, which is the most costly to make by the prevailing boiler tube process, is the cheapest to make by the electrolytic process. M. Bouchayer says that he is able to meet all commercial competition in producing thin tubes, and he plans the construction of a second plant relatively near Grenoble, which would have double the capacity of the present plant.

Process of the Western Electric Company

The research departments of the American Telephone & Telegraph Co. and the Western Electric Co., in seeking a commercial process for the manufacture of pure iron in a pulverized form, employed the very ingenious expedient of utilizing the hardness and brittleness of electrolytic iron from which the hydrogen had not been eliminated, in order to get the material into a finely powdered form and compress it into magnet cores which would have high electrical resistance because the particles were not soft enough to crush together into a unit mass. When these operations were concluded, the compressed cores were baked to remove the hydrogen, leaving pure iron particles.

This process proved cheaper and better than reducing the iron powder by hydrogen from the oxide. A commercial electrolytic iron plant was therefore equipped at Hawthorne, Ill., with a capacity of about 2 tons of iron per day.[3] This method of securing pure iron proved to be relatively inexpensive and to afford a ready means of controlling the quality of the material.

The cores of the loading coils which are introduced at regular intervals to increase the inductance of a telephone circuit are now made of this material. The electrolyte is of ferrous sulphate and chloride and ammonium sulphate; the anode is mild steel; the cathode of polished sheets of steel, from which the deposited metal is stripped when it has reached a thickness of $\frac{1}{8}$ to $\frac{1}{4}$ in.; the current density is about 12 amp. per sq.ft

Electrolytic Iron Direct From Ore

The deposition of iron by electrolysis is from the electrolyte directly on to the cathode. The use of a soluble anode is only a means of keeping the electrolyte supplied with iron. Any other means of accomplishing the same result would give the same depositions, electrical efficiency, etc. For example, the circulation of the electrolyte, always maintaining it up to the desired standard of iron content, would effect the electrolytic action and avoid some disadvantageous features, such

*Reprinted from the Jan. 5, 1922, issue of *Iron Age*. Slightly condensed.

[1]The process and works have been so well described and illustrated in the technical press, and especially by Guillet in *Revue de Métallurgie*, Mémoires, 1915, February, page 82, and by Jean Escard in *Le Génie Civil*, 1919, Aug. 23 and following issues, that details may be omitted here.

[2]Furthermore, a very impure cast iron must not be used, because some of the metalloids will migrate to the cathode.

[3]A brief description of the plant and process is given in the *Journal* of the American Institute of Electrical Engineers, July 1921, pp. 598, 599, 608 and 609. The magnetic and electrical properties of the material and the completed cores are described on pp. 600 to 608.

as the economic waste due to the loss in slimes with the soluble anode, the migration of impurities from anode to cathode, etc.

This is the novelty introduced by Frederick A. Eustis and Charles P. Perin in patents issued the former and developed jointly by them. This process has passed through the laboratory stage and commercial installation is under way. The solution of iron ore is the means of keeping the electrolyte enriched in iron in proportion as it is impoverished by the electrolytic deposition. The electrolyte is ferrous chloride; the anode is of some insoluble material such as graphite; the current density is 50 amp. per sq.ft. The cathode may be a revolving mandrel on which the iron is deposited in the form of a tube, or it may be in the form of a sheet, or a traveling belt from which the crumbs are removed continuously by mechanical means.

The process thus resembles the copper leaching and deposition process so successfully carried out at Ajo, Ariz., and elsewhere, and the established process of electrolytic zinc production. It faces the necessity of producing a metal which must sell in competition at a price lower than that of copper or zinc, but has the advantage of much lower price for ore and absence of some of the chemical difficulties encountered in the leaching and electrolysis of zinc. It may also be employed in localities where iron ore and a market for iron and steel exist, but where solid fuel for smelting is costly. It differs from the usual "direct process" in that it can deliver a product in finished form, ready for market, instead of a "sponge" which is commercially equivalent

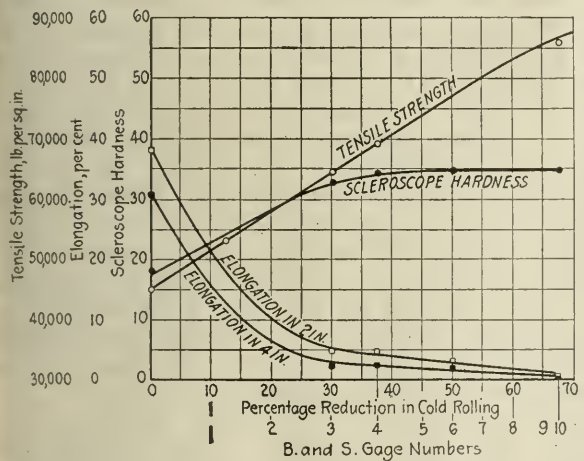

FIG. 1. CHARACTERISTIC CURVES OF ELECTROLYTIC IRON

a poor grade of steel scrap and must be submitted to several processes before it has industrial usefulness. It differs from the electric smelting of iron in that it will produce a very pure product without the use of any flux.

Obviously, it can be applied to any iron ore capable of solution, but its cheapest raw material is the abundant sulphide ores which occur in many parts of the world and which sell at a low price, because, first, of their abundance, and second, their inapplicability to blast-furnace smelting until after a process of complete roasting. Such ores also yield their sulphur content as a byproduct, at a price which more than covers both the cost of sulphur production and the total cost of the ore itself.

The present projected application of the Eustis process is to an iron sulphide ore containing a small amount of copper, and the operations will deliver in marketable form the iron, the sulphur and the copper in one short series of processes.

Pure iron is deposited on the cathode and the ferric chloride formed in the anode compartment is used over again for leaching, thus making the process cyclical. Sulphur is recovered as brimstone and copper is precipitated out on scrap iron. The speed of leaching depends on the fineness of pulverization of the ore, but presents no difficulties whatever after extended laboratory tests, although it is important to avoid unnecessary use of chlorine by mechanically separating such oxides as lime and magnesia before solution. Leaching is assisted by the circumstance that the reaction is

exothermic. Counter-current extraction has resulted in delivering 97 per cent of the iron and 90 per cent of the sulphur content of the ore.

It is unique in metallurgy for one brief cycle of operations to deliver in marketable form more than 90 per cent of any ore. In the electrolytic vats the electrolyte is circulated vigorously, resulting in smooth, compact deposits being obtained; the cathode current efficiency is 90 per cent and over. With proper control no chlorine is lost, or other noxious gases given off. Each step of the process uses standard apparatus which has been developed after years of commercial operation, so that the transition from laboratory to full-scale industrial operation involves no costly experiments.

Purity of Electrolytic Iron

The only serious impurity in electrolytic iron is hydrogen, and this may be entirely removed by baking at a moderate temperature. Traces of other elements may be present by inclusion during deposition, but no great precautions are necessary to produce metal assaying 99.9 per cent and higher. Tubes made at Grenoble and analyzed in America showed 99.97 per cent Fe, and tubes made by the Eustis process assayed 99.99 per cent. It is noteworthy that it costs no more to make the very pure material than to deposit metal of inferior grade, depending upon the process employed.

Mechanical Qualities of Almost Pure Iron

The mechanical qualities of pure iron are greatly affected by heat-treatment and cold-working; furthermore, the presence of hydrogen, due either to original deposition or to absorption at a red heat (for some persons, through inexperience, have "annealed" the metal in hydrogen gas and then tested it tensilely) destroys its strength and renders it both hard and brittle as well. The crystalline structure of the deposited

metal is fairly coarse and well defined. It is refined on appropriate annealing, and, on rolling or drawing in the cold state, it takes a beautiful fine structure and brilliant polish, which is more than ordinarily durable on exposure to the atmosphere, dampness, etc. Naturally this refining of the structure is accompanied by increase of strength.

An average of tests made by the National Tube Co. on tubes made at Grenoble, in the condition in which they were received, showed tensile strength in the direction of rolling 62,000 lb. per sq.in. and elongation of 12 per cent in 8 in.; the average of three tests of similar material, redrawn and annealed at 900 deg. C. for 20 minutes gave 39,000 lb. per sq.in. tensile strength and 30 per cent elongation in 8 in. (See tests 4 and 6 in the table.) The bursting strength of a Grenoble tube 4 in.

in diameter and 0.03 in. thick, reported by Escard in the *Génie Civil* article cited above, was 1,110 lb., corresponding to a fiber stress of 73,500 lb. per sq.in. It is very probable that pure iron, like very soft steel, would increase greatly in tensile strength without losing much in ductility by subjection to a double heat-treatment.

Cold-Working Properties

In *Le Génie Civil* monograph tests are described and photographs given showing the extraordinary softness and cold workability of the Grenoble tubes. Escard says it is the regular practice at Grenoble to draw five

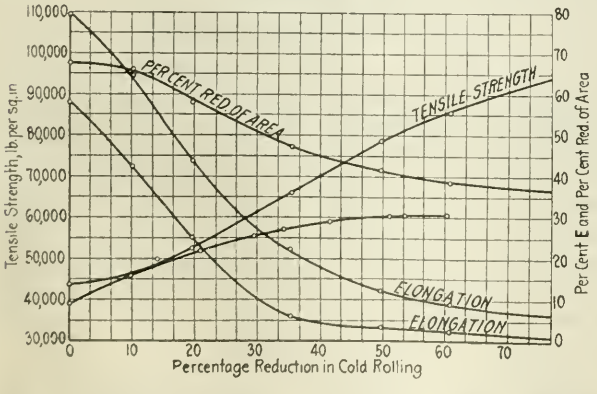

FIG. 3. CHARACTERISTIC CURVES OF TUBING METAL

times through a die without annealing, as compared with the customary practice with soft steel to anneal before each draft. This statement is corroborated by tests made in America, at the plant of the Stanford Steel Products Co., of iron made at Grenoble and iron made by the Eustis process. Tests of cold-rolling, deep stamping after cold-rolling and without annealing, cold-rolling and beading, threading, etc., showed that the electrolytic iron would undergo work with much less frequent annealing than soft, open-hearth steel, and would endure more cold deformation without cracking than ingot iron, Toncan metal, and, in some instances, electrolytic copper.

This softness and ductility open a wide field of usefulness, because the saving in cost of annealings alone (which is an expensive item in cold-rolling work) is an important economic feature, besides the greater ease of working and lessened defective articles. Additional light on the cold-working qualities of pure iron is shown by Fig. 1, "characteristic curve," with which are compared electrolytic copper (Fig. 2) and "tubing metal" (Cu 75 per cent; Zn 25 per cent). The latter is given because its qualities so much resemble those of pure iron.

Resistance to Corrosion

A test made at the Massachusetts Institute of Technology by Prof. Carle R. Hayward showed that a piece of Byer's wrought-iron pipe corroded nearly twice as much, and Shelby steel tubing 2.6 times as much in the atmosphere as electrolytic iron made by the Eustis process. According to the same authority, an immersion test of 22 hours in 5 per cent sulphuric acid gave a ratio of loss of weight per unit of area:

For electrolytic iron	1.00
For steel	4.25
For wrought iron	18.50

Fields of Usefulness

There are many articles whose value is dependent more upon their quality or upon the amount of labor expended on their fashioning than upon the cost of the material of which they are composed. Stamped and beaded articles, like threaded caps, can be made with less annealing and less defective material. The possibility of greater thinness would find its advantage wherever heat conductivity is important, as, for instance, boiler tubes; and even the cook knows that tin cooking utensils bake quicker than aluminum, because they are thinner. The beautiful polish assumed by pure iron after cold-rolling, and its resistance to corrosion, may result in cooking utensils being made without tin, and so perhaps avoiding the color which tinned articles assume after heating and which is the great selling argument for aluminum and nickel utensils.

Thin boiler tubes is a use already mentioned, and involving enormous quantities. Many articles now stamped of copper, because of its softness, could be stamped of electrolytic iron at a greatly reduced price. Where the advantage of increased resistance to corrosion is valuable, there are many uses, such as eaves troughs; boiler tubes (again); pipes and culverts; containers for water and corrosive liquids; parts of automobiles requiring to be bright, ornamental articles to be nickeled and exposed to the weather, where rust soon attacks ordinary steel through its coating and mars its attractiveness; even galvanized, or tinned and painted goods would be more durable if the body of the material were of a less corrosive nature.

Add to this the economic possibility of making electrolytic iron in districts where solid fuel is now too costly for smelting, and we can visualize the commercial advantage of the new industry to localities which already use, or would use, large quantities of articles whose high price is due more to the labor expended on fashioning them than on the cost of the basic material. We are only beginning to secure the information as

to the kind and amount of such articles. Where purity alone is important, we have material like welding wire, for which a fancy price is now paid for relatively pure material. Iron for magnetic purposes has already been mentioned. It is thought that, as greater quantities of pure iron are available for research, investigation will enlarge this field. Electrical conductivity purposes should be included; and, finally, pure material as the basis for the manufacture of high grade, high priced steel for alloy steels, cutting tools, etc.

The "characteristic curves" of electrolytic iron compared with electrolytic copper shown in Figs. 1 and 2 indicate the use of this material in the form of wire for electrical purposes. It is evident that the wire can be cold-rolled so as to have far better tensile properties as transmission lines than electrolytic copper. It will be noted from the previous tests quoted that electrolytic iron has 10 to 20 per cent greater conductivity than steel. It is therefore about the equivalent of copper-clad steel; or the electrolytic iron may be copper clad, thus increasing its conductivity by another 20 per cent or so, and leaving it still not so soft and ductile as to have the objectionable stretching qualities of copper in transmission lines.

Legal Notes

By Wellington Gustin

Test of Unfair Competition Through Use of Some Natural Names in Business

From the United States Circuit Court of Appeals comes an interesting case (271 Fed., 395). A suit in equity for alleged unfair trade competition was begun by the Walker Bros. Co., of Boston, against W. & H. Walker, Inc., of Pennsylvania. This was not a case in which either of the parties resorted to similitude of names for unfair purposes, or of similitude of labels or markings. Both parties had adopted their natural names in their business and defendant was a much older concern. Neither knew of the existence of the other prior to the alleged unfair competition, yet each had been carrying on its business under the name Walker, without fraud, intentional or unintentional, upon each other, and without any substantial confusion or misleading of the consuming public, until the Boston Walkers discovered that the Pennsylvania Walkers were introducing their goods through jobbers and wholesale dealers.

The position of the Walkers of Boston was that under the circumstances they were entitled to the wholesale field in a particular locality, because they were first in that field under the Walker name.

On this proposition the court says such affirmance would interfere with the fundamental rights of reasonable trade competition and with reasonable and commendable purposes of trade enterprise through expansion. However, it is true that business expansion, through instrumentalities in the wholesale and jobbing fields, might be under such circumstances of bad faith, with or without involving deceptive devices, such as similar trade-marks and names, as to make the competition unfair. But none was found in this case.

In some cases of unfair competition the question depends on the purpose or on the good faith or bad faith of the dealers, while in others the question is whether the situation in and of itself, without regard to good or bad faith, is calculated to deceive the public; but the test is always whether trade is being unfairly interfered with, and whether the public is being cheated into buying or paying for something which it is not in fact getting.

Rights After Expiration of Patent Design

In the case of Lenox, Inc., vs. Jones, McDuffee & Stratton Corporation (271 Fed., 511), the Lenox company brought suit upon a design patent, No. 50,064, which had been issued Dec. 19, 1916, under an express term limiting it to 3½ years. The designer was Frank G. Holmes, who assigned his rights to plaintiff.

The design was intended for the face of certain high-grade chinaware. The article was put upon the market as one of great merit, and the sales ran into hundreds of thousands of dollars within a single year.

The court said the chief difficulty of the plaintiff's case was that the patent expired before the menace of infringement claimed by the Lenox company. So the question of unfair competition of the defendants with plaintiff's business became the only serious question involved.

The rights of monopoly, under patents based upon machines, instrumentalities, designs, etc., expire at the end of the term expressed in the patent, and things covered by the patent become public property—provided they are reasonably marked by the name of the manufacturer who adopts them, and are reasonably and properly designated as something made by one, other than the original patentee or producer or manufacturer, by giving the true name of the one who makes them and puts them into the trade, except perhaps in cases exactly like, or perhaps something in very close similitude of, the original in bad faith, to the end that purchasers shall not be deceived into buying a particular thing as an original when it is not.

Case Hinged on Markings

From this law the court said the chief question presented was whether the articles of English manufacture which Jones, McDuffee & Stratton think they may put into their trade are suitably and properly designated as another and as an English product, to the end that they shall reasonably differentiate themselves from the Lenox "Ming." The court found there were considerable differences in the design and coloring in the English and American product, the English ware being of much cheaper grade, selling for one-fifth the price of the American, and the markings on the bottom of the English wares were distinctly different, having the name of the manufacturer and the word "England."

"Patent monopoly," said the court, "was intended by the framers, in the primal sense, among other things to advance science and to encourage invention in respect to instrumentalities, to stimulate original and attractive designs in the field of art, through granting exclusive control to inventors and designers for a limited period. Yet it still remains that it is quite as true, in the broader and more important sense, that there was an intent in the interest of the general public, to the end that the public at large, after the limited monopoly had had its run, should receive the benefits of developments which the government had encouraged through giving exclusive monopoly to inventors and designers for a limited period."

Exclusive control in the Lenox patent had expired by its express terms. Therefore, if there was no wrongful

purpose, the Lenox design, except as to limited qualifications, is open to others. And the court said that if the English product, which the defendant company proposed to use, was suitably marked and designated as English product, so that purchasers would not be led to believe that they were getting the original Lenox "Ming" when in fact they were getting something else, there was no wrong.

Hence the suit against the English company was dismissed.

Protecting Iron With Paint Against Atmospheric Corrosion

SOME experiments in the protection of iron with paint against atmospheric corrosion were described recently to the Iron and Steel Institute (British) by Dr. J. Newton Friend, Carnegie Gold Medalist. These experiments consisted in exposing, for a period of 5 years, a series of plates of steel coated with various paint mixtures, and determining their loss in weight due to corrosion.

These plates measured 2 ft. x 1 ft. x 0.03 in. thick (No. 22, B.w.g.), and were made of open-hearth steel, cold-rolled and charcoal-annealed. They were cleaned by immersion in dilute sulphuric acid, then washed and placed for a few minutes in dilute caustic soda solution to remove any traces of acid. After again washing and drying, the plates were finally polished with emery paper. After weighing and painting, the plates were suspended on a specially constructed wooden fence erected on a low bank running almost due north and south in the valley of the Severn River.

In order that the results might be as reliable as possible and relatively independent of the effects of minor variations in chemical and physical properties from which iron plates are so likely to suffer, five plates were used in each test. Unfortunately, during the absence of Dr. Friend on military service, some of the plates were blown down during gales and damaged. This accounts for the gaps in the table of results.

After 5 years' exposure to the atmosphere the plates were removed, soaked in caustic soda solution to remove the paint, washed, dried and any adherent rust gently rubbed off by scraping and polishing with emery paper.

The oils used in these experiments were:

No. 1. Pure Calcutta raw linseed oil.

No. 2. Same oil as No. 1, heated for 16 hours to a maximum temperature of 305 deg. C. No drier.

No. 3. Oil No. 1, heated for 4 hours with 0.5 per cent Cyprus umber up to 305 deg. C.

No. 4. Oil No. 1, heated for 2 hours with 1.5 per cent manganese hydroxide to 150 deg. C.

No. 5. Oil No. 1, heated for 4 hours with 1 per cent litharge to 205 deg. C.

Dr. Friend has already demonstrated the superiority of polymerized linseed or litho oils over the raw oil for the protection of iron against atmospheric corrosion. This is attributable in part to their diminished permeability toward water, but mainly to their greater stability, polymerization resulting in the saturation of the double bonds, thus rendering the oils less liable to oxidation and disintegration upon exposure.

On the other hand, an ordinary boiled oil is partially oxidized in the process, and, particularly if a drier be present, a marked increase in the rate of setting is observed when the oil is spread as a paint film on a suitable surface. One of the main objects of the "boiling," indeed, is to increase the rate of setting. But the same catalysts which accelerate the setting or initial oxidation also accelerate the disintegration or show further oxidation upon prolonged exposure to air. Hence, in contradistinction to litho oils, ordinary boiled oils will not as a rule offer as good protection to iron as the raw oil. This is shown clearly in the results in Series *A*, *B*, *C*, *D* in the table.

Not only do two coats of paint protect iron from atmospheric corrosion more efficiently than one thinner coat, but they are even slightly more efficient than one thick coat containing the same weight of paint as the two together.

It is important to remember that this applies only to atmospheric corrosion, for Dr. Friend has shown that a precisely opposite effect is obtained by prolonged immersion of iron plates in water. The amount of corrosion under these conditions actually increases with the number of coats or thickness of the paint.

TABLE I—RESULTS OF EXPOSURE TESTS

All weights are expressed in grams. Period of exposure, 5 years.

Series	Composition of Paint by Weight	Wt. of Paint on Each Side	Loss in Wt.	Mean Loss
A	60 red lead / 40 oil No. 1	15	3.35 5.95 3.05 3.50 2.30	3.63
B	60 red lead / 40 oil No. 2	15	.... 5.25 5.82 3.55	4.87
C	60 red lead / 40 oil No. 4	15	7.20 .... 6.62	6.91
D	60 red lead / 40 oil No. 5	15	3.80 6.58 7.10 4.30	5.45
E	First coat: 60 Venetian red / 40 oil No. 3	12	2.25 2.48	2.66
	Second coat: 30 Venetian red / 70 oil No. 3	12	.... 3.25	....
F	First coat: 30 Venetian red / 70 oil No. 3	12	1.35 1.80	1.30
	Second coat: 60 Venetian red / 40 oil No. 3	12	.... 0.75	
G	Two coats: 45 Venetian red / 55 oil No. 3	12 Each	.... 2.28 1.45 2.65	2.13

The question now arises as to whether or not the method of mixing and applying paint to iron may not influence the results. To determine this a series of plates were given two coats of paint, viz:

Series *E*. One coat of 60 per cent Venetian red paint, followed by one of 30 per cent.

Series *F*. One coat of 30 per cent Venetian red paint, followed by one of 60 per cent.

Series *G*. Two coats of 45 per cent Venetian red paint.

It will be observed that the total weight of both pigment and oil on each plate in the three series is the same, but the results are strikingly different. Series *F* yields by far the best results, the thin coat apparently clinging tenaciously to the surface of the metal, while the outer coat, containing a high pigment and low oil percentage, protects the inner by reason of its greater resistance to permeability by moisture and to mechanical erosion.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Dye Investigation Likely to Be Postponed as Sub-Committee Continues to Dwindle

With the announcement by Senator Reed of Missouri that it will be impossible for him to serve on the sub-committee selected to conduct the investigation of the dye situation, Senator Knute Nelson of Minnesota fears that it may be impossible to conduct the investigation at this time. Senator Borah of Idaho, another member of the sub-committee, previously had announced that he could not serve. Thus Senator Shortridge of California, chairman of the sub-committee, is the only member left of the original committee named.

Some of those who were very anxious that this investigation be conducted seem to have lost their enthusiasm since the resolution was broadened to include a probe into the practices of importers and representatives of the German dye interests. On the other hand, the domestic chemical industry appears to be more anxious than ever that the investigation proceed. It is stated that evidence has been uncovered which will reflect unfavorably upon the practices of certain textile concerns and other consumers of dyes. Since the adoption of the Frelinghuysen amendment which extended the scope of the probe to include the importers, some very active work has been done by the domestic chemical industry, with the result that enough already has been disclosed "to hang some of them," as one representative of the chemical industry put it. If this evidence can be brought out before the Senate acts on the tariff, it is expected that it will do more than any other one thing to aid the fight for an embargo.

Licensing of Professional Engineers Subject of Live Debate in Engineering Circles

At the recent meeting of the American Engineering Council of the Federated American Engineering Societies in Washington, a lengthy discussion arose as to the sentiment of the Council regarding the licensing or registering of engineers. Prof. Donald Derickson of Louisiana was the chief advocate of the system, asserting that the experience of his state had been such as to justify the conclusion that the licensing statute had been beneficial alike to the public and the engineer. The Council finally decided to direct the appointment of a committee to make a thorough study of the question.

The Engineers' Club of Baltimore, Md., also recently considered this question and after a thorough discussion of the subject went on record as strongly opposed to any form of state legislation requiring the registration or licensing of professional engineers in Maryland. The opponents of the system, while conceding it would be an excellent thing if it were practically possible for any board to grade each engineer according to his true qualifications and ability, asserted that engineering work is more varied and diversified by far than any other profession and thus it is not to be expected that any state-appointed board could handle the proper grading of individual engineers.

E. F. Smith Addresses Rochester Section, A.C.S.

Dr. Edgar F. Smith, president of the American Chemical Society, addressed the last meeting of the Rochester Section, A.C.S., Dec. 19 at Kodak Park. Choosing as his topic "A Glance at Early Organic Chemistry," Dr. Smith outlined the history of the science and called particular attention to the work of Americans in developing ether, chloroform, synthetic indigo and camphor.

Following this address, motion pictures showing the manufacture of motion picture film at Kodak Park were shown.

Elaborate Program Planned for Meeting of American Ceramic Society

As previously announced, the American Ceramic Society's twenty-fourth annual convention will be held at the Hotel Statler, St. Louis, Mo., Feb. 27 to March 3 inclusive. Three days will be devoted to presentation and discussion of papers on manufacturing problems; two days of open house will be held at industrial plants and seven divisions will meet simultaneously. In addition to the smoker and banquet, exhibits of equipment will be encouraged. The general chairman of the local committee is J. L. Green, 1673 Railway Exchange Building, St. Louis, Mo.

Among the forty papers announced to date are the following:

"The Testing of Silica Brick," K. Endell, Charlottenburg, Germany.

"A New Method of Measuring the Porosity of Brick," E. W. Washburn and E. N. Bunting.

"The Products of the Calcination of Flint and Chalcedony," E. W. Washburn and Louis Navias.

"Refractories Engineering," W. E. Dornbach, Baltimore, Md.

"Comparison of Hot and Cold Modulus of Rupture for Silica Brick," E. N. McGee, Syracuse, N. Y.

"Refractories for Zinc Smelting," George C. Stone, New York City.

"Possibilities of Terra Cotta Casting," R. F. Geller.

"The Cost System as an Aid to Efficient Plant Control," D. T. Farnham.

"The Permeability and Diffusion of Gases Through Refractories," H. W. Douda, Columbus, Ohio.

A number of subjects of timely interest are being prepared for round-table discussion.

Commonwealth Edison Co. Opens New 250,000-Hp. Plant in Chicago

The Commonwealth Edison Co. of Chicago has thrown into operation a new $10,000,000 power plant located in South Chicago on the Calumet River near 100th St. for supplying the industrial district. When this station is eventually completed as planned, it will generate 250,000 hp. With the new plant the capacity of the plants of the Commonwealth Edison Co. now exceeds 800,000 hp. It is planned later to build another 250,000-hp. station on the shores of Lake Michigan at Waukegan with the Public Service Co. of Northern Illinois, which will fit into a scheme of electric superpower development of Wisconsin, Illinois and Indiana. The Chicago system has become the hub of a network of interconnected electric transmission lines in the upper Mississippi Valley which spreads nearly to Minneapolis on the north, southwest to the Mississippi River, and south to the coal fields of Kentucky. The development of power generation on this huge scale is indicative of the industrial growth of this section of the Middle West.

Laboratory Tests for Molding Sand to Be Standardized

A committee, organized by the National Research Council and American Foundrymen's Association, has reached agreement on six tests which will show the properties that are most indicative of satisfactory working conditions of the sand in almost all lines of foundry practice. The "fineness" test and "cohesiveness" test should be given first consideration. Tests for permeability, water content, thermal properties and rational and chemical analyses should also be considered in a general study of molding sands. Information is now being acquired preparatory to drawing up specifications for the proper methods of making such tests.

American Engineering Council Holds First Annual Meeting

The American Engineering Council of the Federated American Engineering Societies held its first annual meeting in Washington, D. C., on Jan. 5 and 6. A leading event of the meeting was a dinner in honor of Secretary of Commerce Hoover at which Mr. Hoover commended the Council's work for the elimination of waste in industry, declaring this to be the most fundamental of all problems with which the nation must deal. He urged the development of methods for effecting economies in manufacture, transportation and distribution and suggested that the problem of national electrification be taken up in the form of a waste survey.

The Council voted to continue support of the legislation for the relief of the U. S. Patent Office as embodied in the Lambert bill. Steps were also taken to co-operate with the Department of Commerce in the movement to prepare for cyclical industrial depressions and unemployment by resort to public works projects. An unqualified indorsement of an embargo on dyes was voted by the Council.

Officers for the year are as follows: president, Dean Mortimer E. Cooley, of the University of Michigan; vice-presidents, D. S. Kimball of Cornell University and J. Parke Channing of New York; treasurer, W. W. Varney of New York; executive secretary, L. W. Wallace.

Steady Business Improvement Indicated by Increased Production in Industries

Ceramic. The five general ware potteries at Sebring, Ohio, are now working at practically full time and expect to maintain production at this status for at least 6 months to come. The different plants are the Sebring China Co., Limoges China Co., Royal China Co., Worcester China Co. and the Saxon China Co.

The Crip Pressed Brick Co., Ennis, Tex., has resumed production at its plant under an operating schedule of about 20,000 bricks per day.

The Haws Refractories Co., Hawstone, near Lewistown, Pa., has resumed operations at its plant after a shutdown for a number of months. Production will be maintained on a basis of 50 per cent for the present.

The majority of potteries at Wellsville, Steubenville and East Liverpool, Ohio, devoted to the production of general ware, have resumed production on a full-time schedule, following a shutdown through the holiday week for inventory and other purposes.

Chemical. The National Aniline & Chemical Co., Wilmington, Del., has added a number of permanent workers to the operating force at its local plant.

Rubber. The Goodyear Rubber Co. is planning for the early resumption of operations at its local plant, following a 2 weeks' shutdown. A wage reduction from 10 to 25 per cent for male operatives at the plant has been announced.

The Goodyear Tire & Rubber Co., Akron, Ohio, has added about 1,000 employees to the working force at its local mills since the middle of December. It is expected to increase the number of present workers soon.

Glass. Practically all of the glass plants in the Wheeling, W. Va., district are now in operation, with production varying from 80 per cent to full capacity.

Glass factory at Sisterville, W. Va., will resume operations Feb. 1 after being idle over a year.

Oil. The Standard Oil Co. has increased the working force at its Bayway refinery, Elizabeth, N. J., to more than 4,100 men, the largest number which has been employed at any one time since last May. The plant is operating on full time.

Paper. The New York & Pennsylvania Co., Johnsonburg, Pa., operating a local paper mill, has increased production to close to capacity.

The Charles Boldt Paper Co., New Iberia, La., manufacturer of paper products, has placed its recently completed mill in operation.

The Trinity Paper Mills, Commerce, Tex., manufacturer of paper pulp from cotton linters, has placed its new mill in operation.

Iron and Steel. The Tennessee Coal, Iron & Railroad Co. and the American Steel & Wire Co., both subsidiary to the United States Steel Corp., are operating their plants in the Birmingham, Ala., district in excess of 60 per cent of normal.

The E. & G. Brooke Iron Co., Birdsboro, Pa., has blown in its local furnace, which has been idle for about 10 months past. Employment will be given to about 130 men.

The Reading Iron Co., Reading, Pa., has resumed operations at its Oley St. mills on a full-time schedule. Plans are under way to place the puddle mills on Ninth St. in service at an early date.

The Allegheny Steel Co., Brackenbridge, Pa., has resumed operations at its plant after a shutdown of a number of weeks. A group of ten sheet mills at the works, now idle, will be placed in service before the close of the month.

The Altoona Iron Co., Altoona, Pa., has resumed production at its local plant after being idle through the greater part of the past year.

The Trumbull Cliffs Furnace Co., Warren, Ohio, will soon blow in its local blast furnace, rated at 600 tons. The plant has been completed at a cost said to be about $3,000,000, and operations have been held in abeyance for some time past owing to conditions.

Outlawing of Chemical Warfare Not Likely to Stop Gas Research by U. S.

Influence on the part of friends of the capital naval ship is said in Washington to have been an important factor in the decision of the Arms Conference to outlaw chemical warfare. When the Chemical Warfare Service demonstrated last summer, in the tests in the lower Chesapeake Bay, that gas could be used effectively against ships, it was not realized, some point out, that it was paving the way for its own destruction. From the date of those tests there has been an increasing animosity to gas in naval circles. This is not confined to the United States, but it applies equally well to many of the advocates of the superbattleship in other countries.

The idea of outlawing chemical warfare had its inception and its chief impetus in the advisory committee to the American delegation. The advisory committee was a sort of afterthought of the conference idea. The committee was selected at the last minute and no advance notice was given those who were appointed to serve. Most of its members took the appointment as complimentary, but a few of those designated took the matter seriously and insisted on advising, much to the embarrassment of certain officials. Senator Sutherland, chairman of the advisory committee, Secretary of Commerce Hoover and John M. Parker, Governor of Louisiana, outstanding members of the committee, are known to have been of the opinion that it would be just as practicable to agree to outlaw war itself. Since Secretary Hoover and Governor Parker are busy men, they devoted very little time to the affairs of the advisory committee. Certain members of the committee, sensing the approval which would follow this course from that portion of the public which had not looked into the subject deep enough to know that chemical warfare is the most humane, efficient and least expensive of all the modern weapons, pressed their report with utmost vigor, it is declared. There has been no explanation as to how General Pershing was induced to reverse himself on the subject. His testimony before the House Committee on Military Affairs just prior to the establishment of chemical warfare as a separate service of the army was an indorsement of a positive character.

Representatives in Washington of the chemical industry point out that the conference would not have thought of concluding an agreement as to the reduction of naval armament unless England, the chief naval power, were to be a party to it. There was no hesitation, however, in attempting chemical disarmament by decree, and Germany, still armed to the teeth chemically, was in nowise considered.

Insufficient time has elapsed to allow any arrangement of details, but since England made the expressed reservation that it would be necessary to keep abreast with chemical development, to guard against the use of gas by an outlaw nation, it is assumed that the United States will not abandon the research work on gas which it now has well under way.

Catalysis and Photomicrography Subjects at New Jersey Chemical Society

Large attendance marked the regular monthly meeting of the New Jersey Chemical Society on Jan. 9, 1922, in Newark, N. J. H. S. Taylor, of Princeton, spoke on "Auto-Catalysis," describing several reactions in which one of the products of the reaction apparently acts as a catalytic agent. Dr. Taylor described some recent experiments on the reduction of cupric oxide by hydrogen and on the efflorescence of cadmium sulphate crystals in support of his contention that in this type of reaction it is only at an interface, where a molecule of the substance is in contact with a molecule of one of the products of its decomposition, that the reaction proceeds.

Charles P. Titus, consulting microscopist, New York, gave a profusely illustrated talk on fabrics, outlining methods of manufacture and showing photomicrographs of numerous textiles.

New York Section of A.C.S. Hears Papers on Glues and Gelatins

The subject at the regular monthly meeting of the New York Section of the American Chemical Society on Jan. 6, 1922, was "Glue and Gelatin." The speakers were R. H. Bogue, Mellon Institute, S. E. Shepherd, Eastman Kodak Co., and E. T. Oakes, National Biscuit Co. Dr. Bogue's paper dealt with the classification of glues and gelatins and is reported in more detail on page 123 of this issue. Dr. Shepherd's paper discussed photographic gelatin, describing the protective action of the gelatin in delaying precipitation, its important effect on the coating operation due to its varying viscosity and the sensitizing or desensitizing effect of gelatin on the emulsion due to the presence of small quantities of metallic impurities, sulphides, grease and organic reducing agents. The talk was illustrated with slides showing curves, photomicrographs of emulsion grains and photographs of instruments used in the Eastman laboratory for determining the setting point, jelly strength and swelling of gelatin.

Potash Producers Hopeful for Adoption of Five-Year Protective Duty

Sufficient sympathy for the domestic potash industry has been manifested by members of the Senate Finance Committee to lead to the belief that agricultural potash will not be returned to the free list. The chances are thought to favor the adoption of the rates contained in the House bill which prescribe a duty of 2½c. per lb. on actual potash for the first 2 years; 2c. per lb. for the third year; 1½c. per lb. for the fourth year; 1c. per lb. for the fifth year, agricultural potash thereafter to be on the free list.

The opposition to this duty came mainly from H. A. Huston, American representative of the German potash syndicate, and from the National Fertilizer Association, represented by S. D. Crenshaw, vice-president of the Virginia-Carolina Chemical Co.

Mr. Huston was frank in his admission that he had been connected with the German potash syndicate for 19 years. He declared that the syndicate had been much maligned and that it is not a monopoly even in Germany. He emphasized the fact that the German law prohibits, under heavy automatic penalties, the sale of potash for export at less than the price offered for potash for distribution within Germany. He argued that it would be to the great economic advantage of the United States to use many times the amount of potash now consumed.

Mr. Crenshaw stated that American producers, in spite of the monopoly given them by the war, had never produced more than 54,000 tons of actual potash in any one year, and that there is no reason to expect that they can produce the normal American requirements at present prices, plus the proposed tariff. He also stated that certain forms of potash much used and desired in the United States cannot be produced in this country. Another difficulty facing American producers is that freight rates alone are nearly as much as the cost of foreign potash delivered at American ports.

Wilbur LaRoe, an attorney, appeared for the United States Potash Producers' Association. He cited the Federal Trade Commission as authority for statements that the Virginia-Carolina Chemical Co. is financially interested in certain German potash enterprises and that it has important holdings in the German potash mines. He declared that the fertilizer interests are leaving the impression, in stating that they have contracted in Germany for only 75 per cent of their requirements, that the remaining 25 per cent may be purchased of American producers. He declared that this is not a fact and that within the last few weeks contracts have been made with Alsatian producers for the remaining 25 per cent of the requirements of the thirty-four companies which entered into the German contract. It was brought out in the hearing that these thirty-four manufacturers produce at least 60 per cent of the country's fertilizer output.

Mr. LaRoe also took exception to the statement by the representative of the fertilizer manufacturers relative to prohibitory freight rates, mentioning the practicability of shipment by water and the promising potash fields in New Jersey as a source of supply for Eastern markets. The domestic supply of potash, he told the committee, is sufficient to meet domestic needs for an indefinite time. The reserve at Searles Lake alone amounts to 20,000,000 tons, he said. Already the solar method of evaporation is being used there with great success and by extending it and providing for increased efficiencies, Mr. LaRoe predicted that the United States within the 5-year period could produce potash at a less cost than can Germany. While all the American plants are closed at present, Mr. LaRoe stated that they have an annual capacity of 100,000 tons and will reopen if the duty is allowed. He estimates American requirements at 240,000 tons. Statements were presented from the State Chemists of the more important fertilizer using states to sustain his contention that California potash is now free of borax. The duty requested, it was stated, will give the federal treasury $10,000,000 annually during the first 2 years. Mr. LaRoe declared that domestic producers are ready to start up their plants if they can be assured of receiving as much as $1.10 for their output.

Short Course in Ceramic Engineering at Illinois University

As previously announced, the short course in ceramic engineering at Illinois University will be conducted this year from Jan. 23 to Feb. 4. This course, as is well known to members of the American Ceramic Society, is designed to meet the requirements of practical men. It deals with the principles underlying the work of managers, superintendents, foremen, burners and others who may be concerned with the manufacture of ceramic products. Those companies who have sent their employees in previous years have been amply repaid for the time and money expended.

The courses this year will be very much on the same basis as in last year's program with some different lecturers and the addition of lectures in business law, boiler water and glass technology. Prof. Charles F. Binns, formerly secretary of the American Ceramic Society, will deliver the lectures on glazes.

National Association of Cost Accountants Conducts Membership Drive

The National Association of Cost Accountants has recently begun a drive for 400 new members by March 1. This organization is national in scope and has members in practically every state in the Union in addition to some in Canada, Mexico and Europe.

There are local chapters in most of the principal cities of the United States. These chapters meet monthly to hear various messages by reputable cost authorities on cost and accounting problems. These local chapters are the clearing houses where cost data and plans are exchanged by representative cost men and accountants.

All those interested in cost accounting are invited to investigate the merits of the organization with a view to becoming active members. S. C. McLeod, 130 West 42nd St., New York City, is the national secretary and business agent.

Ford Muscle Shoals Offer to Be Submitted to Congress by Secretary of War

Secretary of War Weeks, after a conference on Jan. 13, 1922, among Henry Ford, Secretary Hoover and himself, announced that the Ford offer for the Muscle Shoals plant, in the form of a contract, would be transmitted to Congress for action. He declined to make public the nature of his comments on the proposal.

The National Fertilizer Association has undertaken the publication of an analysis of the Ford offer and a survey of the situation surrounding the project, under the caption of "Truth About Muscle Shoals." It is stated therein that Mr. Ford proposes to make two kinds of payments—interest and amortization. The interest payments are a partial reimbursement to the government for the interest which the taxpayers must pay on the money invested in the water power and amount to a total of $161,040,000 over the 100 years' lease. The government, however, must pay interest on $57,000,000 new money invested, which at 4 per cent would amount to $2,280,000 per year. As will readily be seen, this creates a deficit of $600,000 or more every year.

C. W. Goodale Honored for Safety and Welfare Work by Mining and Metallurgical Society

Charles W. Goodale, of Butte, Mont., was awarded the gold medal of the Mining and Metallurgical Society of America at its annual meeting, Jan. 10, for conspicuous services in safety and welfare work. In 1898 Mr. Goodale was appointed general manager of the Boston & Montana Consolidated Copper & Silver Mining Co., operating the richest copper mines in Butte and a large smelter at Great Falls, about 200 miles northeast, a position he filled with great success up to the time of the absorption of that company by the Anaconda Copper Mining Co. Since that time he has been chairman of the Bureau of Safety for all the Montana operations. Those same qualities which have always brought him the affectionate regard of his numberless acquaintances in mining and metallurgical circles have enabled him to enlist that sincere co-operation of all the foremen and workmen so necessary for the success of safety and welfare measures.

Summary of Newly Organized Chemical Firms

During the month of December a total of twenty-six companies was organized to manufacture chemicals, dyes, drugs and affiliated products, with individual capitalization of $50,000 or more. The total indicated capital aggregates $3,595,000. This compares with the formation of thirty-five companies in November, with total authorized capitalization of $6,300,000.

The total for the year 1921 shows an indicated capitalization for new companies organized of $108,410,900, as compared with a capital of $487,148,000 for new concerns in the industry formed in 1920.

Business Paper Editors to Meet

The National Conference of Business Paper Editors will hold a meeting in Washington, D. C., on Jan. 23. After luncheon, the afternoon will be devoted to a conference with the Chamber of Commerce of the U. S., at which will be discussed the railroad situation, tariff legislation, soldier bonus and the hardwood decision of the Supreme Court. The program of the day also includes the regular dinner with Secretary of Commerce Hoover, at which problems of interest will be discussed.

American Ceramic Society Moves Headquarters

Official announcement has been made that the headquarters of the American Ceramic Society have now been transferred from Alfred University, Alfred, N. Y., to Lord Hall, Ohio State University, Columbus, Ohio. Organizing Secretary Ross V. Purdy has automatically, with the coming of the new year, been made general secretary of the society, and his headquarters are at the above address. Charles F. Binns, who has for many years served the society faithfully and well, retired from active participation in the work.

Personal

Dr. Clarence W. Balke, chief metallurgist of the Fansteel Products Co., North Chicago, recently spoke before the American Institute of Mining and Metallurgical Engineers at the rooms of the Western Society of Engineers, Chicago, on "The Story of Tungsten."

S. M. Barnet has been elected president of the Barnet Leather Co., New York, succeeding his father, the late Morris S. Barnet. Sigmund Rothschild was elected vice-president of the company.

C. A. Bigelow, formerly general manager of the Aetna Explosives Co., became assistant general manager of the Hercules Powder Co. on Jan. 1, in charge of the high explosives division. On the same date L. N. Bent became assistant general manager in charge of naval stores, fulminate and caps, and nitrocotton divisions.

R. A. Bull, a consulting engineer of Sewickley, Pa., has moved his headquarters to Spondly Building, 638 Diversey Parkway, Chicago, Ill.

O. S. Delaney, E. I. du Pont de Nemours & Co., Wilmington, Del., gave an interesting address on the subject of the manufacture of explosives at a recent meeting of the Olympia Chemical Club, Tacoma, Wash.

Robert W. Hilton, vice--president of the Ault & Wyborg Co., Cincinnati, Ohio, has announced his withdrawal from the company after 25 years of service. Mr. Hilton started with the company as a chemist and was in charge of the laboratory for 6 years, after which, for 9 years, he was superintendent of the company's plants, and for the last 10 years has been in charge of the development and manufacture of products. After a short vacation he will enter business for himself.

F. Kniffen has resigned as production manager of the cellulose products manufacturing department of E. I. du Pont de Nemours & Co. He will continue to serve that department in an advisory capacity.

Dr. S. K. Loy, chief chemist of the Standard Oil Co.'s (formerly the Midwest Refining Co.) refinery at Casper, Wyo., has been appointed consulting chemist of the Bureau of Mines in connection with oil-shale work.

Thomas O. Marvin has been designated by President Harding to become chairman of the United States Tariff Commission, succeeding Thomas Walker Page, who recently resigned. Commissioner William S. Culbertson has been named vice-chairman.

Ralph H. McKee spoke before the Franklin Institute on Jan. 12, on "Gasoline From Oil Shale."

J. V. Mowe, general sales manager of the Kelly-Springfield Tire Co., Akron, Ohio, has been elected a vice-president of the company.

G. N. Norman, chemical director, and R. S. McKinney, purchasing agent, for the Hercules Powder Co., expect to sail for Europe on Feb. 7. They will be abroad for about 3 months and will visit the principal continental countries.

C. Olin North, C. W. Bedford, R. C. Hartong and C. N. Hand, all formerly connected with the development department of the Goodyear Tire & Rubber Co., have left that organization and incorporated the Rubber Service Laboratories Co. Mr. Bedford is the present chairman of the Rubber Division of the American Chemical Society.

A. L. Pitman has been appointed assistant director of the Bangor station of the Massachusetts Institute of Technology's School of Chemical Engineering Practice.

N. P. Rood, vice-president of the Hercules Powder Co., expects to make a business trip to Chile in the near future.

C. J. Snyder has accepted a position as technical director of the Newman Ice Cream Co. of York, Pa. He was formerly in the chemical department of E. I. du Pont de Nemours & Co. at Parlin, N. J.

Herbert Talley will leave the service of the Hercules Powder Co. on Feb. 1 to go with the U. S. Powder Co.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

The Uneven Fall in the Prices of Basic Commodities

One of the conspicuous obstacles in the path toward better times in business is the maladjustment in the wholesale prices of the principal domestic commodities. The general process of deflation appears to have run an uneven course, so that there exists at the present time an unusual disparity between the great groups of basic materials. The spread between the prices of farm products and other primary materials, on the one hand, and the prices of manufactured goods, labor and transportation, on the other is an obstruction to progress. Substantial revival of business cannot be effected as long as such unbalanced relations continue, and it therefore behooves business to study these fundamental conditions in order that means may be provided for their correction.

Inequality in Recession From War-Time Peaks

Babson's analysis of 78 leading articles of commerce indicates that 39 are from 50 to 100 per cent and 18 from 2 to 25 per cent above the pre-war level. On the other hand, 21 are from 0 to 82 per cent under the 1904-1913 average. This maladjustment of prices is further shown in the price indexes of the U. S. Bureau of Labor Statistics, which are shown in the accompanying table. From the 1920 maximum to the figure reported for November, 1921, these groups have shown the following percentage decreases: farm products 53.7, metals and metal products 39.0, foods 50.5, chemicals and drugs 27.0, fuel and lighting 34.5, and building materials 42.2.

The Collapse of Agricultural Prices

Almost at the bottom of the whole situation is the severe agricultural depression. The farmers produced a bumper crop during 1921, but according to official estimates of the government, their produce had a market value eight billion dollars less than the value of the crop of 1919 and three and a half billion less than in 1920.

The farmer has been forced to shoulder tremendous losses, for practically every farm product is selling for less than the actual cost of production. Furthermore, his purchasing power has been reduced correspondingly and this has necessarily had its effect on practically every branch of industry. It has been estimated by reliable authorities that the farmer's dollar purchases less goods now than it has at any time during the past 30 years.

Chemical and Metallurgical Prices

Metals and metal products have had the next most conspicuous decline of prices. In the index numbers of the Bureau of Labor Statistics this group stands at 119 for November, 1921, in comparison with 114 for farm products and 149 for all commodities. This represents a fall of practically 40 per cent from the peak reached in 1920. Practically every non-ferrous metal is selling at prices which are equal to or lower than the pre-war level.

Chemicals and drugs, according to the Labor Department statistics, are at a somewhat higher level, although still not greatly above the average for all commodities. It is significant to note that the chemical group reached a low of 161 in August of this year and in the three succeeding months for which figures are presented has shown a very slight increase.

The disparity between this figure for chemicals and drugs and the CHEM. & MET. Weighted Index of Chemical Prices perhaps needs some explanation. It should be understood at the outset, however, that these index numbers are obtained by entirely different methods. Although both are based on a somewhat similar selection of commodities, the Bureau of Labor statistics includes among its eighteen items such articles as quinine and opium. Although these may be regarded as indicative of the trend of the drug market, they are nevertheless subject to extreme fluctuations and at the present time demand unusually high prices. As explained in our issue of Jan. 11, the weighted index compiled by this magazine is based largely on such materials as the heavy chemicals and other similar products of quantity output and demand.

INDEX NUMBERS OF DOMESTIC WHOLESALE PRICES
(Compiled by U. S. Bureau of Labor Statistics)
1913 average = 100

Month	Farm Products	Food, Etc.	Fuel and Lighting	Lumber and Building Materials	Metals and Metal Products	Chemicals and Drugs	All Commodities
1913 (average)...	100	100	100	100	100	100	100
1914 (average)...	103	103	96	97	87	101	100
1915 (average)...	105	104	93	94	97	114	101

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	143.75
Last week	144.49
January, 1921	181
January, 1920	242
April, 1918	286

The very slight drop in the index number during the current week was caused principally by the lower prices for soda ash, caustic soda, bleaching powder and methanol. Slight increases in the prices for aniline oil, formaldehyde, glycerine and linseed oil failed to retard this movement.

Solving Some Problems of Unemployment

A plan to take care of the families of employees out of work or on part time has recently been instigated at Lynn, Mass., plant of the General Electric Co.

All workers, including wage and salary earners, submit to a 1 per cent reduction in pay, which is impounded into a fund to be used among the unemployed. This is, however, only a temporary arrangement, since the company has not approved any general plans for unemployment insurance.

To Market Copper Shingles

The Anaconda Copper Mining Co. expects to use more than 30,000,000 lb. of copper this year in the manufacture of copper shingles. Although the initial cost of the new product is about twice that of the ordinary wooden shingle, has the advantages of durability and light weight. The shingles are supplied in natural copper finish and also in seven shades ranging from green to russet brown.

Unemployment During December

Unemployment increased by 4.7 per cent during December, according to the monthly survey of the U. S. Employment Service. The survey covered 1,428 firms located in the sixty-five principal industrial centers of the country. These concerns were employing 1,493,107 workers on Dec. 31.

Increased employment is shown in textiles, iron and steel, lumber, leather, paper and printing and metals and metal products other than iron and steel. The decreases were mainly in the food industries; liquors and beverages; chemicals; stone, clay and glass products; tobacco manufacture; vehicles for land transportation, and railroad repair shops.

German Export Trade During November

A slight decrease in the volume of German exports for the month of November as compared with the previous month has been reported from Berlin by Commercial Attaché C. E. Herring. Percentage decreases as well as increases in the volume of exports for the principal groups of commodities are shown in the following table:

Commodity	Decrease Per Cent	Commodity	Increase Per Cent
Heavy chemicals	12.0	Leather	2.0
Dyes	3.0	Leather goods	14.7
Cotton manufactures	5.4	Rubber goods	5.8

The total imports into Germany decreased more than the exports, with the result that November shows a greatly diminished trade balance by volume.

Three Years' Export Trade in Dyes

Statistics recently released by the Department of Commerce show rather vividly the decline in the value of our exports of dyes and dyestuffs. The commodities shown in the government's classification fell from a total of $30,410,198 for the first 11 months of 1920 to $6,465,665 for the same period of 1921.

The figures for the exports to principal countries show some rather significant changes. The most striking, perhaps, is the tremendous decrease in our dye exports to China. From over $5,500,000 for January-November, 1920, they fell to about $750,000 during 1921. Japan was practically on a par with China in the former year, but in 1921, although her exports were cut in half, she became by far the most important customer for American dyes.

EXPORTS OF DYES AND DYESTUFFS, JANUARY TO NOVEMBER, 1919, 1920 AND 1921.

Total Exports by Classes

	Eleven Months Ended Nov. 30, 1919	Nov. 30, 1920	Nov. 30, 1921
Dyes and dyestuffs—			
Aniline dyes	$9,396,615	$20,662,310	$4,812,122
Logwood extract	1,299,023	2,529,192	545,060
All other	4,654,202	7,218,696	1,108,483
Total dyes and dyestuffs	$15,349,840	$30,410,198	$6,465,665

The New York Market

NEW YORK, Jan. 16, 1922.

Business in the chemical market during the past week was not of large proportions. The industry still shows the influence of the inventory period, but there are some signs of improvement. A tendency still exists to shade prices on some commodities to stimulate trading. Among the most important developments reported was a decline in the prices of caustic soda and soda ash for forward shipments and also an easier spot market for both products. Leading producers are making a great effort to get real business this year and believe that attractive prices are the only means. Numerous inquiries for caustic soda from the Orient have reached the market and a fair volume of business has been placed at slight concessions *Silicate of soda* has been reduced by leading makers.

There has been no change recorded in the chlorate market in spite of the large importation from Germany. Commercial white powdered *arsenic* is considerably higher and in some first-hand quarters it was stated that sales as high as 8c. per lb. have been made. Imported material was quoted at $6.75 per 100 lb. Spot resale arsenic was held at 7@7¼c. per lb. for limited quantities only. Imported *prussiate of soda* has reached new high levels and only a few odd lots were obtainable in the open market. Sales of spot material were reported at 17¼c. per lb. for imported. January shipment is held firm at 17c. per lb., with relatively little obtainable. *Bichromate of potash* is slightly lower at 10½c. per lb. Buyers are not taking much interest in this item at present. Imported white granular *salammoniac* is easier, with shipment material offered at 6¼c. per lb. *Caustic potash* continues to show a strong tendency both on spot and forward shipment. Resale stocks are gradually diminishing and while it is still possible to do 6c. per lb. for the 82-92 per cent imported, 6½c. was asked in leading quarters. Export sales of solid *caustic soda* were reported at $3.60@$3.70 per 100 lb. Goods ex-store were quoted at 3¾c. per lb. Producers quote contracts at $2.65 per 100 lb. f.o.b. works, basis 60 per cent, in carload quantities. *Soda ash* in single bags is moving quietly at $1.75@$1.80 per 100 lb. Sales of soda ash in barrels were reported at $2.10@$2.15. At the works, produers are accepting contract business at $1.35 per 100 lb., basis 48 per cent. *Glycerine*, c.p., was advanced ½c. per lb. on spot and quotations at the end of the week ranged from 16½@17c. per lb. Demand has been much better in this item since New Year's. *Prussiate of potash* continued in its firm position and supplies have practically disappeared in second hands. Manufacturers stated that limited supplies were available at 24½@25c. per lb. The red variety was also available in limited quantities at prices ranging from 29@30c. per lb.

VEGETABLE OILS

Leading crushers of *linseed oil* advanced prices 2c. per gal. to a basis of 71c. per gal. in carload quantities, for prompt and forward shipments, the rise being in sympathy with the seed. The demand, however, fell away at the close of the week and the undertone was barely steady. Bids were in the market at 69c. per gal., but these were turned down. Higher prices for imported oil were a feature of the market. English oil was offered at 62½c. per gal., duty paid, January shipment. Dutch oil was available for prompt shipment at 62c. per gal., duty paid. Sales of spot *chinawood oil* were recorded at 12¾c. per lb. for carload lots. On lesser quantities 13@13¼c. was quoted. January delivery oil closed at 13¾c., with February held at 12¾c. There was a firmer market for crude *peanut oil*, prices closing a fraction of a cent higher on prime goods. Holders of prime stocks were asking 7⅞@8⅛c. per lb., buyers' tanks, f.o.b. mills. Refined oil in barrels, for prompt shipment, closed at 10⅞@11c. per lb. The market for English refined *rapeseed oil* was steady at 82@84c. per gal. in barrels. Dutch oil was offered at 81c. Future prices held around 78@80c. per gal. Scattered lots of resale *soya bean oil* were offered at 7@7¼c. per lb., sellers' tanks, f.o.b. coast. The market was dull and featureless.

The Chicago Market

CHICAGO, Ill., Jan. 13, 1922.

An improvement can be noticed in the general condition of the industrial chemical market, but as yet it has failed to show the big increase of business looked for after the first of January. It is quite evident, however, that better times are coming for the chemical trade, and it is to be hoped that things will pick up gradually rather than all at once. Stocks are all low and a sudden rush of business would surely cause an acute shortage, which in turn would send prices upward. Today prices were noticeably firm, with little or no tendency to shade regular quotations.

General Chemicals

The alkalis are moving only in a routine way and while no pressure to sell was evident several holders reduced their prices. *Solid caustic soda* was quoted at $3.75 per 100 lb. for the 76 per cent material in ton lots and similar quantities of the ground at $4.50. *Caustic potash* is very firm at $6.50 per 100 lb. for 88-92 per cent material. Leading factors in this market expect higher prices very soon due to the increasing costs abroad. *Soda ash* is quoted at $2.60 per 100 lb. basis cooperage and is moving only in small lots.

Potash alum is unchanged as to price and is in moderate demand at 5½@6c. per lb. for the lump and 6@6½c. for the powdered. *Ammonium carbonate* is very quiet and unchanged at 9@10c. per lb. for the lump in casks. *White arsenic* is very firm and material at 7c. was difficult to locate. *Barium chloride* is firm but with a small demand. The imported white crystals are quoted at $60 per ton spot delivery. *Bleach* is firm and is moving in a routine way at 3c. per lb. for large drums. *Copper sulphate* is a firm item and is moving in a fair way at 6c. per lb. *Glycerine* is one of the strongest items on the list and the c.p. material is scarce at 16½@17c. per lb.

Potash bichromate is in fair request, and supplies are available at 12¾c. per lb. *Sodium bichromate* is very firm, and while one factor held to 9c. per lb., most of the others advanced their ideas to 9½c. The *prussiates of potash* continue firm and scarce. The best that could be done on the red was 31c. and on the yellow 26c.

The acid market shows no change and is still very dull. *Acetic acid* is unchanged in price, with very little moving. The same is true of the heavy acids, where only small lots are moving in carboys.

Vegetable Oils

Linseed oil is reported to be moving in a fair way and the inquiry especially from the paint trade to be much improved. The boiled oil is today quoted at 80c. per gal. in 5-bbl. lots and the raw at 78c.

Naval Stores

Dealers in naval stores report business as good. *Turpentine* is receiving a good inquiry and is moving in a satisfactory volume. Today's quotation was 91c. per gal. in 1-bbl. lots. *Rosins* are moving very well and the WW grade is quoted at $9 per 280 lb. in less than carlots.

The Iron and Steel Market

PITTSBURGH, Jan. 13, 1922.

While the finished steel markets are commonly described as having been particularly quiet since the middle of December, there is really a fair amount of business being placed at mills. Buyers as a whole have curtailed their purchases somewhat on account of inventory taking, but the influence of this annual operation is perhaps overrated.

Except for the influence of the winter season the fundamental conditions as to steel consumption are substantially unaltered. Demand for oil country goods, which kept up remarkably well until a few weeks ago, is now lighter, but will presumably resume its former gait before the opening of spring.

Dip in Steel Production

On account of the close connection between the steel mill and ultimate consumption of steel, due to buyers having reduced their stocks to a minimum and adopted the practice of ordering from hand to mouth, frequently in single carloads with mixed specifications, steel production has had a dip in harmony with seasonally decreased consumption that has not ordinarily been noticed at this time of year. Production of steel ingots in October was at the rate of 23,000,000 tons a year, November showing an average rate a trifle higher. The American Iron and Steel Institute report for December, just distributed, giving the production of thirty companies, indicates that the average rate in the month was about 20,000,000 tons, which of course means a considerably higher rate at the opening of the month and a considerably lower rate at the close. From this lower rate a recovery has set in this week. January production may possibly not exceed that of December, but in February and March the rate should easily be as great as the rate in October and November, with chances of further increases.

Little Railroad Buying

While the financial condition of the railroads has been steadily improving, there is still but little railroad buying in steel and steel products. The Union Pacific has ordered 4,500 freight cars and the Illinois Central 2,000. Rail orders for 1922 are being placed with more reserve than expected, but in a year's steel business this is of no material importance, since the difference between a close and a liberal policy in replacements is only a very few hundreds of thousands of tons.

The leading interest has booked a large amount of tin plate business for a single week, from large customers in position to act freely in the light of their business prospects. Sheets are decidedly quiet, but a fair volume of business is being placed. The automobile trade is beginning to buy more freely in sheets and other descriptions of steel. Agricultural implement factories, for many months conspicuous by their complete absence from the steel market, are buying in a very small way. One of the poorest features of the general situation is the inability of the farmer to buy, this being important since normally the farm is a large consumer of steel in varous forms.

Steel Prices

Finished steel prices continue to exhibit the steadiness that has characterized them for several weeks past, the condition being in strong contrast with that seen for many months. Price changes are now quite infrequent, while the margin between prices done on small orders and on large orders is quite narrow. The market in general is quotable as follows: Bars, shapes and plates, 1.50c.; hoops, bands and hot-rolled strips, 2c.; plain wire, 2.25c.; wire nails, $2.50; standard steel pipe, 71 per cent basing discount; black sheets, 3c.; galvanized sheets, 4c.; tin plate, $4.75.

W. P. Snyder & Co., operating the Shenango furnaces, have sold 1,500 tons of bessemer pig iron to an Ohio consumer at $19.50 valley. This is the first sale of bessemer of any consequence for quite a while, and establishes a market price, the market having for some time past been quotable nominal at $20 valley. Basic remains quotable at $18.25 valley, and foundry at $19.50 valley.

Coke

Cornellsville furnace coke has stiffened in the spot market and weakened in the contract market, bringing the two close together, as they should be. It would be difficult now to pick up a regular lot of spot coke at under about $3, while a first quarter contract has been made, with an Eastern consumer, at $3.10. Recently spot coke was quoted as low as $2.75, while at the same time first quarter contracts were made all the way from $3.25 to $3.40 and perhaps $3.50.

Steel Scrap

Dealers freely bid $14.50, delivered Pittsburgh, for heavy melting steel scrap and they might pay a trifle more. On round lots to consumers it is unlikely less than about $15.50 could be done. The mills are not in the market at present.

General Chemicals

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.15 — 1.20
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.18 — .19
Aniline salts	lb.	.25 — .26
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.35 — 1.45
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P.	lb.	.60 — .65
Benzoate of soda, U.S.P.	lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech.	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.70 — .75
Beta-naphthol, tech	lb.	.32 — .34
Beta-naphthylamine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)	lb.	.24 — .26
Cresylic acid, 97–99%, straw color, in drums	gal.	.70 — .80
Cresylic acid, 95-97%, dark, in drums	gal.	.65 — .70
Cresylic acid, 50%, first quality, drums	gal.	.45 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.90 — 1.05
Dimethylaniline	lb.	.40 — .45
Dinitrobenzene	lb.	.21 — .25
Dinitroclorbenzene	lb.	.25 — .27
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.38 — .40
Dinitrotoluene	lb.	.25 — 30
Dip oil, 25%, car lots, in drums	gal.	.31 — 35
Diphenylamine	lb.	.60 — .70
H-acid	lb.	1.00 — 1.10
Meta-phenylenediamine	lb.	1.10 — 1.15
Monochlorbenzene	lb.	.10 — .12
Monoethylaniline	lb.	1.40 — 1.45
Naphthalene crushed, in bbls.	lb.	.07 — .08
Naphthalene, flake	lb.	.07 — .08
Naphthalene, balls	lb.	.08 — .09
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.11 — .14
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17
Ortho-amidophenol	lb.	3.00 — 3.10
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.15 — .20

Ortho-toluidine	lb.	.20 —	.25
Para-amidophenol, base	lb.	1.30 —	1.35
Para-amidophenol, HCl	lb.	1.60 —	1.70
Para-dichlorbenzene	lb.	.15 —	.17
Paranitroaniline	lb.	.77 —	.80
Para-nitrotoluene	lb.	.75 —	.80
Para-phenylenediamine	lb.	1.65 —	1.70
Para-toluidine	lb.	1.15 —	1.25
Phthalic anhydride	lb.	.37 —	.40
Phenol, U. S. P., drums	lb.	.11½ —	.15
Pyridine	gal.	1.75 —	2.75
Resorcinol, technical	lb.	1.50 —	1.60
Resorcinol, pure	lb.	2.00 —	2.25
Salicylic acid, tech., in bbls	lb.	.20 —	.21
Salicylic acid, U. S. P	lb.	.22 —	.23
Salol	lb.	.75 —	.77
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 —	.28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 —	.16
Sulphanilic acid, crude	lb.	.26 —	.28
Toluidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.32 —	.38
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....
Xylene, commercial, in drums, 100 gal	gal.	.33 —	.35
Xylene, commercial, in tank cars	gal.	.30 —	....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0.20 —	$0.21
Beeswax, refined, dark	lb.	.24 —	.25
Beeswax, refined, light	lb.	.28 —	.30
Beeswax, white pure	lb.	.34 —	.38
Candellila wax	lb.	.23 —	.24

Quotations have remained unchanged since our previous report.

Structural Material

The following base prices per 100 lb. are for structural shapes 3 in. by ¼ in. and larger, and plates ¼ in. and heavier, from jobbers' warehouses in the cities named:

	New York	Cleveland	Chicago
Structural shapes	$2.63	$2.78	$2.78
Soft steel bars	2.53	2.68	2.68
Soft steel bar shapes	2.53	2.68	2.68
Soft steel bands	3.13	3.28	3.28
Plates, ¼ to 1 in. thick	2.63	2.78	2.78

*Add 15c per 100 lb. for trucking to Jersey City and 10c for delivery in New York and Brooklyn.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The White Star Cement & Coal Co., recently organized under Delaware laws with capital of $3,000,000, has preliminary plans under way for the construction of a new cement-manufacturing plant in the vicinity of Birmingham, with total annual capacity to approximate 1,000,000 bbl. of material. The main office of the company will be located at Nazareth, Pa. A. G. Connolly is president, and Charles W. K. Shafer, secretary. Richard K. Meade & Co., 11 East Fayette St., Baltimore, Md., are engineers for the project.

California

OAKLAND—Fuller & Goepp, 998 Monadnock Bldg., San Francisco, manufacturers of glass products, have plans under way for the construction of a new 2-story, reinforced-concrete plant at 11th and Jackson Sts., Oakland. Work will be commenced at an early date.

Connecticut

NEW HAVEN — The Seamless Rubber Co., Hallock Ave., manufacturer of small rubber goods, is having plans prepared for the construction of a 1-story addition, 140 x 160 ft., with extension 60 x 60 ft., to be used as a spraying department, estimated to cost about $100,000, with machinery. The company is also rebuilding the portion of its plant recently destroyed by fire, with loss estimated at about $200,000. R. W. Foote, 185 Church St., is architect for the new building.

BRIDGEPORT — The Crane Co. has foundation work under way for the proposed 1-story addition to its local South End metal-working plant, 75 x 175 ft., for a new annealing department. Ten large annealing furnaces with auxiliary equipment will be installed. The extension will cost about $50,000.

Delaware

WILMINGTON—Fire recently destroyed buildings of the New Castle Leather Co. and Hercules Powder Co., East Tenth St., with loss estimated at about $50,000 and $15,000, respectively.

Georgia

MILLEDGEVILLE—The Oconee Brick & Tile Co. is planning for extensions and improvements at the plant of the American Fireproofing Co., recently acquired. The capacity will be increased.

Florida

LEESBURG—The Grass Fibre Pulp & Paper Corp., Leesburg, is considering the construction of a branch plant at Arcadia, Fla., for the manufacture of pulp and paper from saw-grass. E. R. Lacy is vice-president and general manager.

Indiana

INDIANAPOLIS—The Piel Bros. Starch Co., State Life Bldg., has filed plans for the construction of an addition to its plant on Drover St., to cost about $50,000. William F. Piel is president.

Kentucky

ASHLAND—The City Council has commenced the construction of a new filtration plant for the waterworks system, to cost about $250,000, including equipment. E. C. Means is city engineer in charge.

Louisiana

NEW ORLEANS—The Celotex Co., manufacture of wall-board composition products from refuse sugar cane under a patented process, is considering plans for the construction of an addition to its plant for largely increased capacity; it is proposed to double the present output. A bond issue for $500,000 is being arranged to provide funds for the expansion.

LAKELAND—Fire Dec. 31 destroyed a portion of the refinery of the Ingleside Sugar Refining Co., with loss estimated at about $200,000, including buildings and machinery.

MONROE—The Owens Bottle Co., Toledo, O., has acquired property at Monroe as a site for the construction of a new plant for the manufacture of glass bottles and other containers. The proposed works will be equipped to give employment to about 500 men.

Maryland

BALTIMORE — The Sherwood Brothers Co., Garrett Bldg., manufacturer of oil products, has acquired a large tract of land adjoining its plant in the Canton section, for the erection of an addition. A number of new buildings will be constructed and machinery installed, while a group of new steel tanks will be built to increase the storage capacity to about 1,000,000 gal. The company was incorporated recently with capital of $1,000,000.

WESTCHESTER—Fire Dec. 29 destroyed a portion of the rendering plant of Frank Leidy, with loss estimated at about $12,000.

BALTIMORE—The Fitch Dustdown Co., Cincinnati, O., manufacturer of sweeping compounds, is negotiating for property at Baltimore for the erection of a branch manufacturing plant. It will be equipped for a capacity of about 30,000 lb. of material per day. The Industrial Bureau of the local Board of Trade is interested in the enterprise.

Massachusetts

WORCESTER — The American Steel & Wire Co. is completing plans for the erection of a 1-story addition to its North Works, to be equipped as a galvanizing department, estimated to cost about $42,000. Practically all of the equipment to be installed will be electrically operated. The engineering department at the works is also preparing plans for other extensions, estimated to cost in excess of $200,000. Charles E. Goodrich is chief engineer.

FALL RIVER — The Fall River Gas Works has preliminary plans under way for the construction of a new water-gas plant, with daily capacity of about 3,000,000 cu.ft. The board of directors recently voted an appropriation of $500,000 for the work.

Minnesota

BABBITT—The Mesabi Iron Co. is considering the erection of a new concentrating plant at its works, estimated to cost about $30,000. W. G. Swart is general manager.

Missouri

KANSAS CITY—The American Foundry & Mfg. Co., Kansas City Life Bldg., has awarded a contract to William R. Jewell, 227 Rialto Bldg., for the erection of a 1-story foundry and plant, 90 x 140 ft., at 18th and Manchester Aves., estimated to cost about $30,000. The company is also considering the erection of two additional plant units, to cost about $65,000. H. H. Akers is manager.

New Jersey

NEWARK—The Celluloid Co., 290 Ferry St., has filed plans for the erection of a new 1-story plant, 71 x 110 ft., at 65-67 Westcott St., estimated to cost about $45,000.

NEWARK—The J. H. Balmer Co., Passaic, N. J., manufacturer of carthenware bathroom fixtures, etc., has leased a portion of the building at 67 Hamilton St., Newark, for the establishment of a new branch plant. Possession will be taken at once.

MILLINGTON—The Asbestos Materials Co. will make immediate improvements and extensions to the local plant of the Bateman Co., recently acquired, and heretofore devoted to the manufacture of agricultural equipment. An addition will be erected to the main building on Central Ave. Machinery will be installed at an early date and operations inaugurated.

JERSEY CITY—Colgate & Co., 105 Hudson St., manufacturers of soaps, etc., have acquired a 2-story and basement building, with two large wings, at Montreal, Que., for the establishment of a new branch plant. The company is now building an addition to its Jersey City factory to co about $140,000.

New York

BROOKLYN—The Perfect Brick & Ho low Tile Co., 188 Montague St., is takin bids for the erection of a new 1-stor plant on Grand St., 95 x 100 ft., estimate to cost about $25,000. Silverstein & Infar ger, 190 Montague St., are architects.

NIAGARA FALLS — The Internation Paper Co. has awarded a contract to th Electric Furnace Construction Co., 90 Chestnut St., Philadelphia, Pa., for th installation of a new 6,000-kw. electri steam generator at its local mill, wit auxiliary operating equipment.

BUFFALO—The city waterworks depar ment, Commissioner Kreinheder, will soo commence surveys for a new filtratio plant at the foot of Jersey St., near th Porter Ave. pumping station of the wate works, estimated to cost about $4,500,00 An appropriation of this amount has bee arranged for the project.

Ohio

NARLO—Following the recent acquis tion of the Dolemite Products Co., Narl by the Kelley Island Lime & Transport Co Leader Bldg., Cleveland, plans are sai to be in progress to increase the productio of limestone at the local plant, effecting total capacity of about 2,500 tons a da

Oklahoma

PICHER—Fire Dec. 26 destroyed th local Plant No. 2 of the Skelton Lead Zinc Co., with loss estimated in excess o $50,000, including equipment.

TULSA—Cosden & Co. are planning fo a number of extensions in their local o refinery, estimated to cost in excess o $1,000,000. The Eastern office of the com pany is at 120 Broadway, New York.

Pennsylvania

PITTSBURGH—The Standard Sanitar Mfg. Co., Bessemer Bldg., has awarded contract to the B. A. Groah Constructio Co., 847 West North Ave., for the con struction of a 1-story addition to its san tary ware-manufacturing plant on Preb Ave., 115 x 130 ft. It will be equippe as a plating department.

PHILADELPHIA—The David Berg In dustrial Alcohol Co., Delaware Ave. an Tasker St., has acquired property adjoinin its plant, 460 ft. wide, and of irregula depth, for a consideration said to be $155 000, and will use the site for expansion.

Tennessee

CHATTANOOGA—The Central Glass Co 4240 Ogden Ave., Chicago, Ill., with plan at North Chattanooga, has acquired th local works of the DeCamp Glass Caske Co., which has been under a receivershi for about a year past, with J. H. McCallun acting as trustee in bankruptcy. The ac quired plant represents an investment o over $200,000, and was secured for a con sideration said to be about $55,000. It wil be used by the new owner for the manu facture of glass caskets, glass shingles and kindred products. It is purposed to inau gurate operations at an early date.

LAFOLLETTE—The Lafollette Coal & Iron Co. has preliminary plans under way for the construction of a new byproduc coke plant at its local works. The main feature of operation will be devoted to fue carbonization, with output to aggregate over 400 tons per day. The plant is esti mated to cost in excess of $500,000. Parke & Wilder, Cincinnati, O., are engineers.

Texas

PORT NECHES—The Humphreys-Pure Oil Refineries Corp., recently organized under Delaware laws with capital of $50,000,000, is selecting a site at Port Neches for its proposed new oil refinery, on the Gulf. The plant is estimated to cost close to $1,000,000, and will form the terminus of the company's new pipe line from the Mexia fields. It will be operated in conjunction with a proposed oil refinery at Houston, Tex., estimated to cost a like amount. Colonel E. A. Humphreys is president.

Virginia

NEW MARKET—Fire Jan. 4 destroyed a portion of the flour mill of M. Driver & Bro., Lacey Spring, near New Market, with loss reported at about $25,000.

Washington

SEATTLE — The Goodyear Rubber Co. has leased a new 2-story factory, 50 x 110 ft., to be erected by the Great Northern Construction Co., New York Bldg., at Terry Ave. and Harrison St., for the establishment of a local works.

Capital Increases, Etc.

THE STORM STEEL BALL CO., 621 Harr Pl., Oak Park, Chicago, Ill., has filed notice of increase in capital from $150,000 to $250,000.

THE MIDDLE STATES OIL CORP., Ardmore, Okla., is arranging for an increase in capital from $16,000,000 to $30,000,000.

THE RUBBER SHOCK INSULATOR CO., a Delaware corporation, has filed notice of intention to operate in New York for the manufacture of rubber specialties, with capital of 2,500 shares of stock, no par value. W. Gutterson, 252 West 64th St., New York, represents the company.

THE INTERNATIONAL PAPER CO., 30 Broad St., New York, N. Y., has arranged for a bond issue of $12,500,000, for financing, general operations, etc.

THE GUNNASH CHEMICAL WORKS, 67 Margaretta St., Newark, N. J., has been declared insolvent, with liabilities totaling about $11,000 over assets.

THE ASSOCIATED PRODUCING & REFINING CORP., St. Louis, Mo., manufacturer of oil products, has filed notice of increase in capital from $2,000,000 to $50,000,000.

THE SKELLY OIL CO., Tulsa, Okla., has arranged for a bond issue of $3,500,000, the proceeds to be used for financing, general operations, etc. W. G. Skelly is president.

The tannery of the VICTOR LEATHER CO., Auburn St., Allentown, Pa., manufacturer of glazed kid, bankrupt, will be sold by the receiver, George H. McNeely, 172 North 11th St., Philadelphia, Pa. The sale will include buildings, land and machinery.

THE HOLLAND-ST. LOUIS SUGAR CO., Holland, Mich., operating refineries at Decatur, Ind., and St. Louis, Mich., has arranged for a bond issue of $1,300,000, the proceeds to be used for financing, general operations, etc.

New Companies

F. R. HENDERSON & CO., INC., New York, N. Y., has been incorporated with a capital of $1,000,000, to manufacture rubber products. The incorporators are F. R., H. H. and B. W. Henderson. The company is represented by Rose & Paskus, 128 Broadway, New York.

THE BIG MARIE OIL CO., Orange, Tex., has been incorporated with a capital of $100,000, to manufacture petroleum products. E. C. O'Neal is president, and P. B. Ryan, vice-president, both of Beaumont, Tex.; and C. G. Sprague, Sour Lake, Tex., secretary-treasurer.

THE STERLING BRICK CO., 5201 Twelfth St., Detroit, Mich., has been incorporated with a capital of $25,000, to manufacture brick and other burned clay products. The incorporators are Harry T. Jenney, E. M. Crider and E. M. Heffron, 5282 Trumball Ave.

THE CELLULOSE PLASTICS & CHEMICALS, INC., Orange, N. J., has been incorporated with a capital of $100,000, to manufacture artificial leather and kindred products. The incorporators are E. A. Mau, C. M. Switzer and Oregon Helfrich, 575 Nassau St., Orange.

B. CANNON & CO., INC., Brooklyn, N. Y., has been incorporated with a capital of $52,000, to manufacture glue, gelatine and kindred products. The incorporators are W. C. Burton, A. Ellis and W. Cunningham. The company is represented by F. J. Knorr, attorney, Albany, N. Y.

THE BEVERLY CHEMICAL CO., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Frank W and William J. Sullivan, 12 Stoughton St., Medford, Mass. The latter will act as president and treasurer of the company.

STRONG & CO., INC., Wilmington, Del., has been incorporated under state laws, with capital of $1,500,000, to manufacture refined oil products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE W. J. EARLY SONS' FOUNDRY CO., Pittsburgh, Pa., has been incorporated with a capital of $60,000, to manufacture iron, steel and other metal castings. J. E. Early, 312 South St., Pittsburgh, is treasurer.

THE SCHULZ CHEMICAL CO., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are C. Schulz, S. N. Johnson and S. D. Strawgate. The company is represented by J. C. L. Daly, 375 Fulton St., Brooklyn.

THE SHAW PAPER BOX CO., Pawtucket, R. I., has been incorporated with a capital of $50,000, to manufacture paper boxes and kindred products. The incorporators are William H. M. Moies, Robert S. Emerson and Charles K. Shaw, Pawtucket.

THE AMERICAN-MEXICAN REFINING CO., 11 South LaSalle St., Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture refined oil products. The incorporators are Henry L. Blim, Norman O. Johnson and D. A. Tasiopoulos.

THE NYOKALA OIL CO., Hamburg (Erie County), N. Y., has been incorporated with a capital of $500,000, to manufacture refined oil products. The incorporators are G. W. Morris, W. Allen and F. J. Carr. The company is represented by A. L. Stratemeyer, Hamburg, N. Y.

THE EASTERN STEEL & WIRE CO., Newark, N. J., has been incorporated with a capital of $1,000,000, to manufacture steel and kindred products. The incorporators are John H. Mesiter, R. Notkin and A. MacMillan. The company is represented by Bilder & Bilder, 790 Broad St., Newark.

THE MEAKIN SOAP CO., Pittsburgh, Pa., has been incorporated under Delaware laws, with capital of $50,000, to manufacture soaps and kindred products. The company is represented by the Capital Trust Co., Dover, Del.

THE CASTING & SUPPLY CO., 239 Washington St., Jersey City, N. J., has been incorporated with a capital of $50,000, to manufacture iron, steel and other metal castings. The incorporators are J. M. and George M. Bachert, and Herman Traeger.

THE BRAZOS OIL CORP., Houston, Tex., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are K. K. Kennedy, T. Lowell Hughes and E. N. Chapman, all of Houston.

THE WATERTOWN PAPER STOCK CO., Watertown, N. Y., has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are J., N. and S. Stabins. The company is represented by Pitcher & O'Brien, Watertown.

THE PURITAN PAINT & COLOR CO., Brooklyn, N. Y., has been incorporated with a capital of $10,000, to manufacture paints, colors, varnishes, etc. The incorporators are W. F. and R. Wolter, and M. Schmidt. The company is represented by Fiero & Fiero, 2 Rector St., New York.

THE FOREST PAPER CO., Portland, Me., has been incorporated with a capital of 5,000 shares of stock, no par value, to manufacture paper products. W. B. Nulty is president, and W. S. Linnell, treasurer. The company is represented by William S. Linnell, Portland.

THE MAGUIRE TIRE & RUBBER CO., Wilmington, Del., has been incorporated under state laws with a capital of $5,000,000, to manufacture automobile tires and other rubber products. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE QUEBRACHO PRODUCTS CO., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture tanning extracts and materials. The incorporators are N. A. Randall, P. J. Haley and H. A. Smith, 39 Cortlandt St., New York.

THE UTILITIES OIL & REFINING CO., Mexia, Tex., has been incorporated with a capital of $150,000, to manufacture refined oil products. The incorporators are F. M. Bransford, E. H. Fielder and H. D. Dines, all of Mexia.

THE SPEIDEN-WHITEFIELD CO., New York, N. Y., has been incorporated with a capital of $60,000, to manufacture chemicals and affiliated products. The incorporators are E. K. Speiden, L. M. Whitefield and A. E. Adams. The company is represented by A. Simmers, 95 Liberty St., New York.

THE ALINALL MFG. CO., Worcester, Mass., has been incorporated with a capital of $24,000, to manufacture paints, colors, etc. Everett H. Hall is president; M. G. Allen, vice-president; and Walter B. Allen, Worcester, treasurer.

THE GROESBECK STANDARD BRICK CO., Groesbeck, Tex., has been incorporated with a capital of $40,000, to manufacture brick, tile and other burned clay products. The incorporators are E. Raphael and Joseph Jolesch, both of Groesbeck.

THE-ECONOMY INK TONING CORP., Valley Stream (Nassau County), N. Y., has been incorporated with a capital of $10,000, to manufacture inks, chemicals and affiliated products. The incorporators are M. I. and J. Kahn. The company is represented by Alexander Rosenbaum, 233 Broadway, New York.

THE STRUCTURAL GYPSUM CORP., Jersey City, N. J., has been incorporated with a capital of $1,125,000, to manufacture gypsum products. The company is represented by the Registrar & Transfer Co., 15 Exchange Pl., Jersey City.

THE CALTEX OIL CO., San Antonio, Tex., has been incorporated with a capital of $80,000, to manufacture petroleum products. The incorporators are H. L. Schermerhorn, A. D. Cummings and J. F. Carl, all of San Antonio.

THE JACKSONVILLE CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are N. Sacks, A. Rosenthal and H. C. Lindgren. The company is represented by Joseph Schottland, 160 Broadway, New York.

THE UNIQUE OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $1,000,000, to manufacture refined oil products. The company is represented by the Corporation Service Co., Wilmington.

THE LAMOLE PRODUCTS CORP., New York, has been incorporated with a capital of $20,000, to manufacture chemicals, dyes, etc. The incorporators are M. Lake, A. S. Molnar and O. S. Leazay, 319 East 24th St.

THE CHATHAM CHEMICAL CO., Savannah, Ga., has been incorporated with a capital of $150,000, to manufacturer fertilizer products. The incorporators are George E. Cope, Gordon L. Grover and W. B. Stratford, all of Savannah.

New Publications

BOOKS

A LIFE OF GEORGE WESTINGHOUSE. By *Henry G. Prout, C.E., A.M., LL.D.* 375 pp., illustrated. New York: Charles Scribner's Sons, 1922. Price, $2.50.

This life of George Westinghouse is the second in what may be a series of biographies of great men associated with the American Society of Mechanical Engineers. Mr. Westinghouse left no written record except in the files of his numerous companies. He wrote almost no private letters. He kept no journals or even notebooks. He made but few addresses and wrote few papers. Accordingly it was necessary to draw upon the many men still living and working who were close to Westinghouse. It was the duty of Mr. Prout as editor to digest these contributions, to co-ordinate them, and to keep a reasonable perspective. In this he was aided by the committee of the American Society of Mechanical Engineers appointed for that purpose: Charles A. Terry, chairman; Paul D. Cravath, Alexander C. Humphreys, James H. McGraw, Charles F. Scott, Lewis B. Stillwell, Ambrose Swasey, with Henry Herman Westinghouse always in consultation.

Mr. Westinghouse's activities were so varied that a chronological narrative would of necessity lead to some confusion. For this reason, each topic has been treated by itself and one has but to glance at the chapter headings to realize the tremendous activity and breadth of vision of this great pioneer. The air brake and friction draft gear naturally take first place, followed by the electrical and related activities—the induction motor and meter, the rotary converter, lighting, power transmission, electric traction, steam and gas engines, the turbo-generator, signaling and interlocking. Natural gas and other interests are considered in separate chapters. There are also general chapters on the European enterprises, financial methods, personality and meaning of George Westinghouse. In an appendix are given chronological and classified lists of his patents.

TRANSACTIONS OF THE AMERICAN ELECTROCHEMICAL SOCIETY, vol. 38. 462 pp., illustrated. Published by the American Electrochemical Society at the office of the secretary, Lehigh University, Bethlehem, Pa. Price, $3 to non-members, $2.50 to members, $2 to libraries, colleges, etc.

This volume contains the papers presented at the thirty-eighth general meeting, Cleveland, Sept. 30, Oct. 1, 2, 1920.

THE MINERAL INDUSTRY DURING 1920, Vol. 29. Edited by *G. A. Roush, A.B., M.S.*, associate professor, department of metallurgy, Lehigh University. 907 pp., illustrated. New York: McGraw-Hill Book Co., 1921. Price, $10.

Statistical, technical and commercial data for 1920 are given for the following: Abrasives, aluminum and bauxite, antimony, arsenic, asbestos, asphalt, barium and strontium, bismuth, borax, bromine and iodine, cadmium, cement, chromium, coal and coke, cobalt, copper, cryolite, feldspar, fluorspar, fullers earth, gold and silver, graphite, gypsum, iron and steel, lead,

magnesite, manganese, mica, molybdenum, monazite, nickel, petroleum and natural gas, phosphate rock, platinum, potash, precious stones, quicksilver, radium, selenium and tellurium, sodium salts, sulphur, pyrite and sulphuric acid, talc and soapstone, tin, titanium and zirconium, tungsten, uranium and vanadium, zinc. The book also includes a chapter on ore dressing and coal washing, and a supplementary chapter of mineral statistics.

STUDY QUESTIONS IN ELEMENTARY ORGANIC CHEMISTRY. By *Alexander Lowy, Ph.D.*, assistant professor of organic chemistry, University of Pittsburgh and *Thomas B. Downey*, M.S., instructor in organic chemistry, University of Pittsburgh. 91 pp. New York: D. Van Nostrand Co., 1921. Price, $1.

The study questions in this book are divided into forty-five groups covering the entire field of a general elementary course in organic chemistry. They are designed to aid the students in mastering the subject more thoroughly, and have been used for this purpose with marked success at the University of Pittsburgh. An excellent bibliography of works and periodicals on pure and applied organic chemistry suggests material for collateral study.

OIL SHALES. By *H. B. Cronshaw, B.A., Ph.B., A.R.S.M.* 80 pp. with map. London: John Murray, 1921. Price, 5s.

This is one of the series of monographs on mineral resources with special reference to the British Empire prepared under the direction of the Mineral Resources Committee of the Imperial Institute with the assistance of the scientific and technical staff. After discussing the occurrences, characteristics and uses of oil shales in a general way, the sources of supply are considered in more detail, one chapter being devoted to the British Empire and another to foreign countries. Then follow a world map showing the location of oil shale districts and six pages of references to the literature on oil shales.

THE DESIGN OF STEEL MILL BUILDINGS AND THE CALCULATION OF STRESSES IN FRAMED STRUCTURES, fourth edition, rewritten. By *Milo S. Ketchum, C.E.*, director of the department of civil engineering, University of Pennsylvania. 632 pp., 60 tables, 410 illustrations. New York: McGraw-Hill Book Co., 1921. Price, $6.

This book covers the calculation of the stresses in framed structures, and also the design of buildings having a self-supporting steel frame with a light covering, usually fireproof. In this edition the book has been rewritten and enlarged, the type has been reset and the plates have been recast. The scope of the book has been enlarged by the addition of a concise discussion of the calculation of the stresses in statically indeterminate trusses and frames, several problems in framed structures and detailed designs of a crane girder, a roof truss, and a steel frame mill building. The book is written to serve as a text book in structural engineering and also as a book of reference for engineers. A complete specification for steel frame mill buildings is given in an appendix.

LABORATORIES: THEIR PLANNING AND FITTINGS. By *Alan E. Munby, M.A., F.R.I.B.A.* 220 pp., 165 illustrations. New York: D. Van Nostrand Co., 1921. Price, $6.

Literature on the subject of laboratories is surprisingly incomplete and scattered. Indeed, the author states in the preface that "search has not revealed any work now in print published in this country [England] which endeavors to deal with laboratories in a manner calculated to bring a building committee, a professional staff and an architect on common ground for what is essentially a joint undertaking." The volume opens with a historical introduction by Sir Arthur E. Shipley, ex-vice chancellor of Cambridge University. The subject is then treated by topics as follows: Scope and Inception of Building Schemes; Requirements of Chemistry; Requirements of Physics; Requirements of Biology and Geology; Laboratory Services; Recent Designs. Excellent descriptions and detailed drawings of typical laboratories in England, the United States and on the Continent make the book of great practical value to those interested in the design construction and equipment of laboratories.

ELEMENTARY CHEMICAL MICROSCOPY, second edition, partly rewritten and enlarged. By *Emile Monnin Chamot, B.S., Ph.D.*, professor of chemical microscopy and sanitary chemistry, Cornell University. 479 pp., 162 illustrations. New York: John Wiley & Sons, Inc., 1921. Price, $4.25.

This book is intended to serve as an introduction to the microscope and its accessories as tools for the chemist to work with and even though practical applications are referred to, the author has made no effort and has no desire to have the book take the form of a manual of industrial microscopy. The changes in this edition have been chiefly in the rearrangement of the chapters, in the elaboration of the data presented and in the rewriting of obscure passages. Comparatively little new apparatus has been described or new methods introduced. A brief synopsis of the course in introductory chemical microscopy as now given at Cornell University has been inserted in the appendix.

In order to meet the often expressed needs of advanced students and of professional chemists, a Handbook of Microscopic Qualitative Analysis is in preparation which will be copiously illustrated by microphotographs and which will thus serve to supplement the present introductory text.

CHEMICAL AND METALLOGRAPHIC EXAMINATION OF IRON, STEEL AND BRASS. By *William T. Hall*, associate professor of analytical chemistry, Massachusetts Institute of Technology, and *Robert S. Williams*, associate professor of analytical chemistry and metallography, Massachusetts Institute of Technology. 501 pp., 183 illustrations. New York: McGraw-Hill Book Co., 1921. Price, $5.

This volume of the International Chemical Series by the translators of Bauer and Deiss's "Sampling and Analysis of Iron and Steel" is divided into two parts.

Part I covers the chemical analysis of iron, steel and brass, and includes the determination of the following elements in iron and steel: C, Mn, P, Si, S, Cu, Cr, Fe, Ni, Mo, W, V, Al, As, Ti, N, O, Zr. A chapter is devoted to the electrometric methods applicable to iron and steel analysis and this part of the book closes with two chapters on the analysis of non-ferrous alloys.

Part II deals with the application of metallography to the inspection and sampling of alloys. The topics are as follows: Preparation and Examination of the Specimen; Metallographic Constituents of Iron and Steel; Wrought Iron and Steel; General Study of Steel With the Microscope; Metallographic Examination of Iron; Gray Iron; Sampling of Iron and Steel; the Alloys of Copper.

A MANUAL OF FLOTATION PROCESSES. By *Arthur F. Taggart*, professor of ore dressing, Columbia University. 181 pp., 56 illustrations. New York: John Wiley & Sons, Inc., 1921. Price, $3.

As indicated by the title, this book attempts to review the entire field of flotation. Its purpose is, in part, to counteract the further spread of false conception concerning flotation concentration, by setting forth some of the essential facts which contradict them; in part to describe apparatus and methods of testing which will aid investigators in their own researches; finally, to give some generalizations from mill practice, by means of which the laboratory experimenter can translate his results into commercial operations. The four chapters of the book are: Introduction, Testing Laboratory Equipment, Testing, Mill Data.

ELECTRODEPOSITION AND ELECTROPLATING. A General discussion held at Sheffield, November, 1920. Reprinted from the *Transactions* of the Faraday Society, vol. 40, part 3, 1921. 83 pp. Published by the Faraday Society, 82 Victoria St., London, S. W. Price, 10s. 6d.

This is a reprint of papers and general discussion presented at a symposium on the subject held by the Faraday Society. The following papers are included: "Electroplating for the Prevention of Corrosion," by Leslie Aitchison; "Some Applications of Electrodeposition in Aeronautical Engineering," by W. H. Thain; "Electrodeposition of Cobalt," by Byron Carr; "Commercial Electrolysis of Zinc Sulphate Solutions," by Samuel Field; "Deposition of Gold-Silver Alloys," by Samuel Field; "Use of Colloids in the Electrodeposition of Metals," by W. E. Hughes; "Electro Silver Plating: Its Technical Development," by W. R. Barclay; "The Chemical Composition of Old Silver Plating Solutions," by G. B. Brook; "A New Maximum Current Density in Commercial Silver Plating," by Frank Mason; "The Crystalline Structure of Electrodeposited Silver," by G. B. Brook.

PROCEEDINGS OF THE AMERICAN SOCIETY FOR TESTING MATERIALS, vol. 21, 1921. 1,197 pp. Published by the Society, 1315 Spruce St., Philadelphia, Pa.

This volume contains the proceedings of the twenty-fourth annual meeting, held at Asbury Park, N. J., during June, 1921, a meeting which was reported in CHEMICAL & METALLURGICAL ENGINEERING for June 29, 1921 (vol. 24, p. 1,145). It contains 441 pages devoted to the reports of committees. Four hundred pages are devoted to nearly 100 tentative standards, proposals printed for one or more years, with a view of eliciting criticism. Many of these have to do with methods of testing, the most elaborate being for methods of analysis of aluminum and its light alloys. Another long specification concerns rubber-insulated wire. The remainder of the book contains the technical papers read and discussed.

Manufacturers' Catalogs

PENNSYLVANIA PUMP & COMPRESSOR CO., Easton, Pa., has issued Form 102, superseding Form 101, on Pennsylvania air compressors and vacuum pumps, both power- and steam-driven in straight-line, single-stage types. The Pennsylvania construction is described in detail and illustrations are given. Copies will be sent on request.

THE CALORIZING CO., Pittsburgh, Pa., in a 4-page booklet describes Calite castings for use in high temperatures, and also its characteristics and physical properties. The General Electric Co.'s research engineers have spent many years to get this alloy, which is claimed to stand high heat.

SCHUTTE & KOERTING CO., Philadelphia, Pa., has just issued a new catalog on heat-transfer equipment. This book contains Bull. 10 DE, on evaporators, heaters and distillers; Bull. 10 F, on heaters for water and fuel oil; Bull. 11 T, on Thermofan system for heating ships; Bull. 12 C, on heat exchangers for recooling oil; Bull. 12 G, on heaters and coolers for air and gases; Bull. 12 R, on multitube motor radiators. Each is descriptive, and well illustrated. This is a reference volume which should be valuable to any plant engineer who is interested in heat transfer as applied to fuel oil systems, heating liquids, feed water, etc.

THE BETHLEHEM FOUNDRY & MACHINE CO., Bethlehem, Pa., calls attention to an attractive catalog on chemical equipment of metal. Illustrations and descriptive matter are given on nitrators, sulphonators, reducers, vacuum stills, washers, autoclaves, etc.

THE ATERITE CO., INC., Paterson, N. J., in Bull. 8 describes and illustrates Aterite and Fanosite valves, cocks, fittings and specialties for manufacturers and users of chemicals.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Cleveland, O., during the week of April 24, 1922. Meetings will be held in the spring instead of in the fall as heretofore.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN WOOD PRESERVERS ASSOCIATION will hold its annual meeting Jan. 24, 25 and 26 at the Hotel Sherman, Chicago, Ill.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Why Prices Are Up or Down

IT IS useful to make a comparison now and then between what we used to expect would occur and what actually has occurred. Our disposition to repose confidence in current appraisals of what is going to come is increased or decreased according to whether or not observation of the phenomenon shows that there is agreement with the prediction.

A year ago it was a common saying that this time we knew why business was poor; it was because men were waiting for declines in prices and wage rates. When proper adjustments had been made, business would resume at its former gait, only at the right prices and costs.

A survey of the situation does not indicate that this appraisal was correct. Some prices have come down very nearly to pre-war levels, others are below pre-war average prices. Some prices are still very high. According to the theory, the lower priced commodities would be moving freely, men having taken hold again, while the higher priced commodities would be moving slowly because of men refusing to take hold on account of not having got what they wanted. This, however, is not the case. While the general average of commodity prices at wholesale, as reported by the Department of Labor, has averaged about 150 since last May and stood unchanged at 149 for November and December, building materials are about double price, and advanced from 197 in November to 203 in December. Next to "house-furnishing goods," which have been at 218 in the past 2 months, building materials are the highest priced class of commodities in the Bureau of Labor's list of nine groups.

Now it is a fact that there has been a very fair volume of building activity lately. There has not been much factory and bridge construction, but there has been activity in erection of garages, dwelling houses and public buildings. The reasonable assumption is that SMITH is like JONES. JONES hopes that prices and wage rates in general and SMITH'S in particular will come down, but he feels individually that JONES is all right and ought to maintain his position as much as possible. If people will buy from him at high prices, he is justified in accepting the money.

People have been buying building materials fairly well. The builder of a garage or dwelling house wants the new facility before he grows any older. The municipality finds it can borrow money to advantage, by tax-exempt bonds, and goes ahead. These buyers do not wait, and so building materials remain at their inflated price levels.

This explanation does not fit all cases, of course. There are some instances, no doubt, where sellers of a commodity are close together and are able to hold up prices by refraining from indulging in strenuous competition. In some commodities, like steel and zinc, there is particularly keen competition, and prices are low. Zinc, after having advanced in recent months, is still well below its pre-war average.

The rule that obtains among sellers of commodities obtains also with workmen, only it is applied in a less practical and intelligent manner. The unions have held wages up where they could, even though they have had little employment. Between 60 and 70 per cent of the bituminous coal-mining capacity of the country is under union auspices and the men adhere to their scale, with the result that the great bulk of the coal being produced today is at non-union mines. The unions in the building trade have submitted to slight reductions only, but they manage to get employment while they are not on strike.

Prices and wage rates that are up are up because they could be held up. Prices and wage rates that are down are down because they could not be held up. There has been no general leveling force. It has not been a case of the general value of the dollar increasing. The value of the dollar, as compared with pre-war times, depends on what you wish to spend it for.

The Value of Personnel Boards

ON THE initiative of the always lively and interesting General CHARLES G. DAWES, Director of the Bureau of the Budget at Washington, a Federal Personnel Board has been established under the supervision of the United States Civil Service Commission.

It is indeed high time that such a board should be established. It is to have, among other duties, the "operation of a service through which employees may be assigned to the several departments or establishments in periods of maximum load, thereby permitting appropriations for the several offices to be made on the basis of their normal loads." It is also to include the training of employees for their positions and to adopt, as far as practicable, "the principle of promotion from within in filling the higher positions in the service with a view to offering a career to properly qualified persons who enter the public service."

This is good business and applied psychology. Now we should like to see another Personnel Board organized among bankers and dealers in investment securities and money lenders to select suitable and qualified directors for industrial corporations so that, when the leaders assume the privilege of naming directors to look after their interests, they may select men who have a reasonable sense of what is required of them. Many directors of great corporations are grossly overpaid by their fees of $10 or $20 a month or a quarter for their services. Others would be grossly underpaid by fees of a thousand dollars per meeting.

Varieties and Vanities Of Millionaires

AT A DINNER of the Alumni of the Massachusetts Institute of Technology held in Cambridge the other day, one of the speakers who made an address in lighter vein offered a little dissertation on Millionaires: Their Varieties and Their Vanities. We venture to repeat a few of his observations for what they are worth, inasmuch as nearly all of us occasionally seek access to millionaires, and when we meet them we usually want the interview to be of an agreeable nature. We are also likely to be ambitious to induce them to accept our own point of view.

Of course they are of all sorts, but an effort was made to discover some of their common traits. Among these is a general conservatism of disposition and that measure of nervousness about property that follows responsibility. Since the only enduring wealth is that of the mind and all other possessions easily take wings, and millions are not mental, this nervousness is justified.

With responsibility comes the consciousness of it, which frequently engenders vanity. One of its most persistent manifestations has to do with the etiquette of calling. If, let us say, a chemical engineer wishes to bring together millionaires A and B who might become jointly interested in an enterprise, he may count on the response from A that "Mr. B knows where to find me; I shall be glad to meet him whenever he calls," and exactly the same from B in regard to A. Neither will call on the other. But both will lunch together without losing face, and whether one or the other pays for it or the engineer himself pays for it, is unimportant.

Habits of speech are to be observed carefully. If the man of wealth is precise in language it behooves the interviewer to call to service all the grammar he knows, and to avoid any solecism; otherwise he will be classed as an inferior person and cannot possibly get in on the ground floor. On the other hand, if the interviewer's speech is more precise or more elegant than that of the rich man, he is in danger of being classed as a theorist, and 90 per cent of our millionaires hate theorists. This expression of hatred of theorists is rather a fashion of speech than a reasonable conclusion, but its use is well-nigh universal, and it serves as a substitute for thought. Such substitutes for thought are more potent to engender obstinacy than earnest deliberation. It is therefore held to be preferable to refer to every measure proposed in regard to apparatus or materials or plant as "the practical application of science."

By association with bankers the millionaire gets the banking habit of mind. Here we meet subjects that we have frequently discussed editorially. We shall merely repeat as blind spots of the banking mind the belief that a balance sheet tells everything; the lack of appreciation that it is only a record of past performances; and the curious illusion that a man who achieves success in one enterprise is almost certain to succeed in another. What is missed is that the very stratagems which apply successfully in one affair will lead to failure in another. The man who has succeeded, for instance, in the manufacture of silk ribbons has a far more difficult path to succeed in garbage disposal than the one who has worked his way along to the administration of the affairs of either of the two fields of activity.

A passion generally caught from banking associations is to "cut out dead wood." Nine men of wealth out of ten, in approaching a reorganization, do not object to their own lack of specific knowledge of the proposed undertaking, but at least eight of them will insist on having a hand in "cutting out the dead wood" if they are to participate in the subscription. It is therefore of leading importance to fix upon some part of a proposed undertaking which the underwriters may have the satisfaction of discovering, as dead wood, and cutting out. If they cannot satisfy this passion, they are likely to break off negotiations. They do not seem to care so much what the dead wood is, so long as they can cut. This they feel they must do. If the engineer does not select it, they will; and as likely as not it will be the very heart of the business.

Some day when bankers get a background of chemistry, millionaires will see the need of it, too. Then chemical industry will have smoother sailing.

Chemistry By Mail

LATELY we protested against a French advertisement offering American university degrees for sale. With equal fervor we object to a misleading announcement in a number of popular American magazines offering to prepare subscribers to earn big money in chemistry by means of correspondence. This consists of thirty-one lessons and lasts 8 months, with the intimation that the subscriber will be a chemist at the end of that time. Salaries of $10,000 to $15,000 a year are set forth as available, to all appearances, to those who take the course. "If your present earnings do not suit you," says the precious booklet which is sent to inquirers, "if you cannot seem to get ahead or do not earn enough to enjoy life, take up chemistry and fit yourself in a few short months to enter a profession which offers unlimited opportunities for sure and rapid advancement."

There's little use in giving more details. They charge $125 for the course, with special discounts for those who make haste to subscribe. The method is a "direct short-cut with all frills and useless details eliminated." No physics, no physical chemistry, no mathematics beyond simple arithmetic—less indeed than may be found in any $2 textbook; and all for $125, which includes the "outfit"—"six test tubes, one glass stirring rod, two glass funnels" and some other things.

The advertisement emanantes from a "Chemical Institute of New York, 140 Liberty St. T. O'Conor Sloane, A.B., A.M., Ph.D., LL.D., Educational Director." The picture of Dr. Sloane is given, which shows him to resemble G. B. Shaw, and it is stated that he was formerly treasurer of the American Chemical Society. A quotation from "Who's Who in America" relates that he made his Ph.D. at Columbia University in 1876 and that he taught natural science at Seton Hall, which is a reputable Catholic school for boys at South Orange, N. J. Inquiry brings out the fact that about 25 years ago Dr. Sloane was treasurer of the American Chemical Society for a short time. He has written some elementary books on electricity, and we are informed that they are not without merit. We know nothing against his earlier career. What appears probable is that in his later years he has got into bad company. Surely no reputable chemist would lend his name to this sort of thing.

We want to do everything we can to advance the teaching of chemistry, so that the public may understand what the science means. But in our judgment this advertisement is misleading. It seeks to get money out of young men under false pretenses, which is a mean trick that should be stopped.

Psychological Adventures in Stupidity

PROFESSOR LEWIS M. TERMAN contributes to the January number of *The Scientific Monthly* an essay entitled "Adventures in Stupidity," which relates to an inferior student called "K." How K managed to slip through high school and graduate at the age of twenty is not given, although the eminence and wealth of his father may have had something to do with it.

He was well brought up, handsome, rather engaging in manner and generally prepossessing in appearance. But after a couple of weeks' experience one of the instructors asked Professor TERMAN to look him over, saying he had never met anyone so stupid. He proved to have a mental age of ten to twelve years, despite the fact that he could read, write and spell acceptably, could drive his high-power motor car as well as the average person, was diligent in his work, and had abundant mental equipment to be, for instance, a champion athlete. At the end of the first term he failed in all his studies and was glad to go home and be a clerk in his father's store. He had not wanted to go to college anyway.

The tests as recorded are involved in psychological jargon that is unfamiliar to most of us, but we can give a few notes that illustrate his intellectual stature. Asked to read a newspaper article and report on it, his replies were childish and inaccurate. He could sometimes carry out instructions if given in a fifteen-word sentence, but if the sentence was thirty or forty words long he would respond with a blank stare. He could not take a mixed sentence, such as "people are many candy of fond," and arrange the words to mean something, because he cannot profit from logical cues. He thinks New York is the largest city in the country "because it covers such a large area." Even his grasp of familiar words is hazy. For instance, lecture means "to be taught," ramble "to go fast," conscientious "very good in his work," brunette "white" and tolerate "to get away from." Summing up, he "lacks intellectual initiative, planning range and flexibility of association, analysis of a situation into its elements, alertness and the direction of attention toward the significant aspects of experience. He is unable to master the intellectual shorthand of general ideas."

Well, how many of us can do these things? It is said with no little authority that the great majority of our high school graduates are drawn from the best 25 per cent of our population, and that the typical university graduate ranks in intellectual endowment well within the topmost 10 per cent. "K is stupid only by contrast. Only occasionally does an individual of his moderate ability manage to graduate from high school or enter college. . . . K is only moderately less dull [*sic*] than the average of the genus homo, judging from intelligence scores made by nearly 2,000,000 soldiers. His intelligence is probably not equaled or exceeded by more than 70 per cent of our white voters by more than 50 or 60 per cent of semi-skilled laborers. It is probably not equaled or exceeded by more than 30 to 40 per cent of our South Italian or 20 to 30 per cent of our Mexican immigrants. Compared with the average American negro K is intellectually gifted, being equaled by probably not more than 10 to 15 per cent of that race."

Professor TERMAN'S conclusions are also interesting. He says K is now a clerk in a general store, and apparently making good. There is no reason why he would not make a reasonably good baker, barber, bricklayer, butcher, carpenter, drill-sharpener, freight checker, game warden, glass blower, harness maker, horse clipper, jail keeper, lathe hand, policeman, professional ball-player, plumber, prize fighter, pedler, railway brakeman, riveter, roofer, section boss, soldier, street-car conductor, timer, truckman, valet, weaver or yardman. or one of a large variety of clerks. He can be loyal to a political party, but he cannot grasp political principles. He can repeat a political slogan, but he cannot understand it.

In short, K represents upward of 50 per cent of the people in his lack of what we call, generically, sense. If we entrust him with work that calls for thinking and judgment, he will fail. If he fails, it may cost us, to put it bluntly, all kinds of good money. He is one of possibly 50,000,000 persons in America who "lack the intellectual shorthand of general ideas"; who can't sense things so as to know what's what.

There's no use getting angry at such folks; the incidence of our wrath should be on ourselves when we entrust them with responsibilities which they are not equipped to meet. It also explains why things happen in Russia as they did when a "dictatorship of the proletariat" was established. K represents the preponderant majority of the proletariat.

Real Progress in Industrial Standardization

DURING December there was held at the Bureau of Standards a conference on sizes and specifications for dry cells, at which a large number of industrial representatives co-operated with the bureau in formulating a revision of the specifications which are recommended by that institution.

One of the most far-reaching influences which will come from the conference was the adoption of recommendations regarding a limited number of standard sizes of batteries and dry cells. Thus all but two of the larger sizes and all but five of the flashlight sizes were dropped from the lists that will hereafter be known as "standard" sizes of dry cells. It was found that this limited number of sizes represented substantially all of the important commercial business of the country. Of course this limited number of cells permits combination into a wider variety of batteries, and for this purpose three flat, three tubular and one box type batteries were recognized for flashlight purposes and two types of radio battery assemblies were also recognized as combinations of the smaller cells. Similarly several combinations of the larger cells were recognized as standard battery assemblies. But all in all the number of stock types which must be kept under these recommendations is very greatly reduced from the old practice.

Industry can well welcome this sort of progress. It is the truest form of assistance and co-operation on the part of the government and one for which the industries may ask greater attention in the future. Nothing has contributed so much to American success as the ability to accomplish mass production, with a minimum of profit on each of a large number of units. This can be done only if the variety of units is made a minimum.

Other industries may well "take their cue" from the battery business and see if they too may not accomplish as much in this way as is promised by these recommendations recently adopted in that field.

Readers' Views and Comments

College Degrees for the Credulous

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Dec. 7, there appeared an editorial, "College Degrees for the Credulous," based on an advertisement from the columns of *Chimie et Industrie*, published by the Société de Chimie Industrielle at Paris. This advertisement promised French chemists doctor's degrees from an American university, "officially recognized," by the simple process of correspondence and presumably for a suitable fee. As president of the American Section of the Société I could not fail to take notice of your editorial, and promptly brought the matter to the attention of its secretary, M. Jean Gerard, from whom I have just received a reply, the translation of which I herewith inclose. I am asking you in fairness to our French colleagues to have the goodness to publish M. Gerard's letter, as I think it will not only be greatly appreciated by them as a courtesy on your part, but I think it will be of more than passing interest to your readers.

I am sure that French chemists in general will be glad that this matter has received so much attention. The editorial which will appear in the January number of *Chimie et Industrie* on this matter will place them on their guard against advertisements of that nature and I know that American chemists will be thankful to you and to *Chimie et Industrie* for protecting the fair name of their universities against unscrupulous degree factories.

J. E. ZANETTI.

Columbia University,
New York City.

Jan. 3, 1922.

MY DEAR PRESIDENT: Your letter of Dec. 1 reached me safely and has received my most careful attention.

The small advertisement of which you speak was accepted by an advertising agent knowing little of scientific questions, and he accepted it without thinking that its insertion would cause annoyance to our American friends.

I beg you to believe that I sincerely regret the insertion of that advertisement.

You know what admiration our journal *Chimie et Industrie* entertains toward American universities. In no case would we be willing to hurt in any way the excellent reputation which they enjoy in our country, and we try on the contrary at every chance that we have to increase that good reputation.

The relations that we have with American chemists individually and collectively are the best proof of our desire to continue and to increase between our nations an intellectual collaboration, which would contribute in the greatest possible way to scientific progress.

It is in this spirit that I believe it my duty to bring to your attention that besides the campaign by advertisements, numerous French chemists have been approached with circulars, of which the following is typical:

> SIR: I beg to call your attention to the advantages that would accrue to you in the exercise of your profession from the acquisition of the degree of Doctor in Chemistry from a university officially recognized in the United States.
>
> As General Delegate of the Orientale University of Washington, D. C., I gladly place myself at your disposal for all information and requirements in this matter.
>
> The diploma may be obtained by the method of correspondence in about three months.
>
> (Signed) COLLEREDO.
> Villa Bella Vista,
> Roquebrune, A. M.

As in our country we are not very well informed about the mechanism of American universities, it would be desirable that this question should be elucidated by you personally in an article that you would prepare and which we would most gladly publish in the economic section of our journal. This question will in addition be treated in an editorial in our next number over the signature of M. Charles Lormand.

I beg to express my sincerest wishes for the excellent relations between American and French chemists.

(Signed) JEAN GERARD.

Sulphuric Acid Air Lift

To the Editor of Chemical & Metallurgical Engineering

SIR:—I notice in the third of the series of interesting articles on "Recent Developments in the Sulphuric Acid Industry," by A. M. Fairlie, published in your issue of Nov. 23, 1921, that a description is given of a so-called Bihn-Jones automatic air device for elevating sulphuric acid which it is stated was first marketed in 1915. As a matter of fact the device described appears to be identical with that introduced 22 years ago by William Barnes, at one time foreman plumber of the Muspratt Works, Widnes, England, and which has been used universally in the works of the United Alkali Co. as well as by other acid makers for the last 20 years. The device is an admirable one and has the advantage of being adaptable to the acid eggs already existing in practically all sulphuric acid works. Apart from the wear and tear when used on very small eggs and from occasional trouble through particles of grit interfering with the action of the float or the back pressure valve it gives no trouble at all. The automatic elevator was never patented by the United Alkali Co., by whom Albert Jones was at one time employed.

My only reason for writing is to point out that the device is scarcely a novelty or recent development, and to insure the credit for its invention being given in the proper quarter—namely, to William Barnes.

Widnes, England. C. S. IMISON.

The Manufacture of Naval Stores From the Dead Wood of Southern Pines

To the Editor of Chemical & Metallurgical Engineering

SIR:—C. M. Sherwood in his article on "The Manufacture of Naval Stores From the Dead Wood of Southern Pines" makes the statement that the composition of pine oil is rather uncertain and mentions only one probable constituent, terpineol. In Schimmel & Co.'s semi-annual reports, April, 1910, eleven different constituents of pine oil were reported. Six of these, however, were really turpentine constituents, since they had boiling points below 177 deg. C. No quantitative data were given, but apparently the most important constituents were identified. This work was not only abstracted in *Chemical Abstracts* but was also mentioned in detail in Forest Service Bulletin 105, on "Wood Turpentines." This bulletin might also have given Mr. Sherwood more information on the comparative composition of wood and gum turpentine than he seemed to have at his disposal.

We will agree that the origin of pine oil is still a mystery, but from the information given in Bulletin 105 it seems very doubtful that it "is present in the living tree as an essential oil and is not a product of

ıydrolysis or oxidation." Since the oleoresin produced n a longleaf pine tree does not contain pine oil, as is ;hown from the composition of gum turpentine, it is lifficult to see how pine oil can be anything else except ın alteration product of the original oleoresin. That he final resin contained in the stumpwood is a prod- ıct of gradual change from the original fresh oleoresin s indicated by the fact that the crude wood turpentine rom the steam distillation of green sawmill waste con- ains very much less pine oil than that from stumpwood, nd also from the fact that the turpentine from this awmill waste is more like the gum turpentine in that t contains so small an amount of dipentene that it annot be readily recognized.

Very few writers on the subject seem to know that he first extraction plant to use the Yaryan process was uilt at Cadillac, Mich. This was not an experimental lant, but was of full commercial size and operated uccessfully for some time. The quality of the wood vailable, Norway pine stumps, was, however, so poor nat with the declining prices for turpentine and rosin was necessary to suspend operations.

L. F. HAWLEY,
In charge Section of Derived Products.
Forest Products Laboratory,
Madison, Wis.

o the Editor of Chemical & Metallurgical Engineering

SIR:—One cannot dispute the statement by Mr. Haw- y that commercial pine oil contains several distinct)mpounds. We endeavored to make this clear in the rticle on naval stores, but did not care to mention the nstituents other than terpineol, because Teeple and)ch have shown quite conclusively that this compound rms by far the greatest percentage of the high-grade mmercial oils, the quantity of other constituents de- nding largely on the degree of fractionation.

While there is no doubt that oleoresin contains no ne oil, it is acknowledged that wood from the same ee, upon being steam distilled, will show considerable ne oil. It was our theory, therefore, that pine oil is t a product of oxidation or hydrolysis, but rather an sential oil of the trees. Neither theory has been oved or disproved, and therefore we are inclined to nsider the origin of pine oil an unsolved problem.

We have had the pleasure of reading Forest Service lletin 105, written by Mr. Hawley, and believe that me very valuable facts for wood turpentine producers ve been brought out. As he points out, the product ries so much in different methods of manufacture t it is difficult to make any certain statements re- rding the composition. Even with the same general cess, the turpentine may be of an entirely different aracter under varying conditions of operation. It for this reason that it is essential to insist upon uni- m methods of operation in plant practice. We have ced in our experiments that under certain conditions a refined turpentine will be obtained which has a grav- it of 0.860 at 15.5 deg. C., while another one with a most an identical boiling range, refractive index and ymerization residue has a gravity of 0.864 when the ration is conducted slightly differently. In the latter e there is probably only a very small percentage of dipentene, while in the former the percentage of dipen- ene is probably quite large. In short, the character wood turpentine varies so greatly under different nditions of operation and refinement that we did not el justified in discussing it in more detail than given the article.

C. M. SHERWOOD.
Brunswick, Ga.

The Six Blind Men and the Jellyphant

To the Editor of Chemical & Metallurgical Engineering

SIR:—Our good friend Jerome Alexander has been seriously ill, but now I am glad to say he is back at work again, busier than ever with colloidal aggregates and their dispersions. While he was mending, feeling the Muse of Poetry hovering nigh, he bade the ghost of John Godfrey Saxe approach and after duly polite acknowledgment to him for his lead in form, he hearkened to the Muse and wrote. Then, having finished the work, he conjured up the shade of Samuel Taylor Coleridge for aid in developing a marginal syllabus which was duly added to the poem. It occurs to me that you should publish it to tell the world how many sided colloid chemistry is.

MARTIN SEYT.

The Six Blind Men and the Jellyphant

BY JEROME ALEXANDER

There were six men of chemistry
To research much inclined
Who went to see the Jellyphant
(Though all of them were blind),
That each one by observing well
Might satisfy his mind.

The old professor rendereth an opinion.

The first approached the Jellyphant
And, happening to note
Its thirst for sour and basic things,
At once began to gloat.
"I see," quoth he, "the Jellyphant's
An ampholytic goat!"

Hofmeister observeth the ampholytic function.

The second, happening to touch
Th' amino acid paws,
Exclaimed, "This is a biped which
Obeys all biped laws!
To call it quadruped shows lack
Of reason or of cause."

The younger Ostwald declareth the Jellyphant to be a beast of froth and foam.

The third said, "Every housewife knows
Why mayonnaise stands up.
Well-made emulsions don't fall out
When you invert the cup.
'Tis plain the Jellyphant is an
Emulsoid-colloid pup!"

W. B. Hardy declareth the Jellyphant to be a bony beast.

"I feel a firmness," said the fourth,
"That seems to indicate
A solid backbone in the beast.
I have it! Sure as fate,
The Jellyphant is really a
Suspensoid vertebrate!"

T. B. Robertson and Mistress Lloyd would have the Jellyphant to shift its innards.

The fifth deaminized its arms,
But still it quenched its thirst,
Whereat they cried, "This hootch-
hound is
Of all we've seen the worst!
It's a keto-enol chameleon.
Deny this fact who durst!"

Jacques Loeb shooeth back the prodigal Jellyphant into the chemical fold.

The sixth immersed the Jellyphant
In water—without malt,
And heard it sing H-ion hymns
In tune, without a fault.
"Now, of a truth," he cried, "this beast's
An orthodox old salt!"

And so these men of chemistry
Disputed loud and long.
Each in his own opinion was
Exceeding stiff and strong.
And each was partly in the right,
Though all of them were wrong.

So, oft in scientific wars
The disputants, I ween,
Neglect, the while they make their
notes,
What all the others mean,
And so describe a Jellyphant
Which none of them has seen.

German Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

ESSEN, Dec. 22, 1921.

THE chemical industry in general is suffering severely from a scarcity of fuel and although the larger works have made themselves partly independent from coal by acquiring extensive lignite deposits, their supply is inadequate since the railways are also hampered severely by lack of fuel. The acuteness of the situation is further accentuated by the low water in the inland waterways, which prevents boats from carrying full cargoes, thus increasing freight rates.

SUGAR

The prospects for the 1921-22 season in the sugar industries are considered a distinct improvement compared with the last outputs. The harvested acreage of sugar beets has increased by a little over 22 per cent and will be equal to an increase of 13½ per cent in the sugar production. Though the production reached its lowest level in the harvest of 1919-20 and has been recovering gradually ever since, the figures are still far from the pre-war production. It must be remembered, however, that Germany has lost a vast amount of sugar beet acreage on account of the peace treaty. While in 1919-20 the sugar output dropped to ⅕ of the pre-war figure, it is fully expected that the output of the present season will be equal to ⅔ of the 1913-14 figure. The production will in all probability just cover the inland requirements and obviate any importations of cane sugar from abroad. Of course, nothing will be left over for export and by government order sugar is excluded from import as well as from export. While immediately before the war, Germany's share in the sugar production of the world amounted to 11.9 per cent or 25.2 per cent in proportion to the beet sugar industry, these figures dropped to 4.6 and 21.5 per cent respectively, while for the present season these figures stand at 8.1 and 26.2 per cent.

NITROGEN FERTILIZERS

The fact that the combined German nitrate producers had entered into an agreement with the English and American producers not to underbid the current prices of the world markets has alarmed the consumers so much that they brought the matter to discussion in Parliament. The farmers naturally got nervous in the expectation that such a stand on the part of the producers might also reflect upon the inland prices, and an assurance was given to control inland prices to a certain extent as well as to regulate the quantities eventually admitted for export. Several cargoes of nitrate have been imported from Chile at a time before the mark dropped out of proportion of its value altogether, but even by allowing for these conditions it is quite out of the question for the farmers to buy the stuff. It is not used as a fertilizer but is worked up as a raw product for the manufacture of concentrated nitric acid. The demand for fertilizers has at the same time slackened considerably and the German ammonia syndicate formed an affiliated company under the name of Nitrogen Credit Co., Ltd., with a capital of 500 million marks which will enable the farmers to buy nitrate fertilizers on long terms of payment, will help to bridge temporary financial difficulties and will also help to increase the consumption of nitrate fertilizers.

The Oppau plant is recovering gradually from the recent disaster and part of it will be restarted within the next few weeks for the manufacture of nitrates. The Oppau disaster, in which the plant was insured only in small proportion to its actual value, has drawn the attention of the workmen's organizations to the fact that large companies, particularly in the chemical industry, are gradually breaking away from the practice of insuring their plants and instead accumulate certain reserves under the heading "self-insurance." While in the Oppau case this self-insurance could easily be borne by a company as strong financially as the huge chemical combine (although even in this instance the accident is cited as a reason for a further increase in capitalization), the workmen are beginning to fear that in the event of a similar disaster occurring in the plant of a company less sound financially this self-insurance might prove insufficient to rebuild the plant so that the company would be compelled to dismiss its men suddenly. The matter of compulsory state insurance has been brought up in Parliament.

SULPHUR

While the German chemical industry as a whole is practically independent of import of raw materials the sulphuric acid industry is in this respect a great exception, being almost entirely dependent upon the import of pyrites. The available raw material in Germany consists of zinc ores, the quantities of which are, however, quite insufficient to meet the demand of the chemical industry. Sulphur ores are imported mainly from Spain and from Scandinavia. Owing to the unfavorable rate of exchange the import of these ores has not reached half the pre-war figure, but preference is given to Scandinavian ores over the Spanish ones, contrary to pre-war practice. The consequent high prices of sulphuric acid and the inadequate quantities available have given fresh impetus to the utilization of sulphur contained so abundantly in the coal and in blast-furnace slag either to manufacture sulphuric acid or to combine the sulphur directly in another form. None of the processes so far suggested has reached a commercial stage as yet.

PHOSPHATES

Phosphates manufactured from the natural calcium phosphate also demand a very high price due to the fact that the raw material mentioned must be imported from the United States or from North Africa. The dependence of Germany from these sources is felt the more as other phosphate fertilizers such as the basic slag, a byproduct in steel works, must now be imported to a greater extent owing to the loss of so many steel works in Lorraine, Luxemburg, Upper Silesia and the Saar district in consequence of the peace treaty.

TAR PRODUCTS

The market for tar products is very firm of late, due probably to the fact that an agreement with France has been reached regarding the compulsory supplies of tar and tar products as outlined in the Versailles treaty, so that deliveries have been commenced. Like every other branch of industry the tar industry is severely hampered by a scarcity of railway cars because the railways cannot get sufficient coal. This scarcity has been temporarily so great that the railway authorities were even compelled to resort to war measures in requisitioning coal on the lines to be able to keep moving, much to the detriment of the works to which such coal was consigned.

Recent Progress in Electrical Precipitation

Brief Description of the Electrical Field Existing in a Cottrell Precipitator—Reduction in Efficiency Found to Be Due to Back Ionization on a Non-Conducting Plate—Development of a Relation Between Electrode Size and Precipitation Rate

By EVALD ANDERSON

THE commercial development of electrical precipitation during the 12 or more years that have elapsed since Dr. Cottrell conceived and built the first successful commercial precipitator has been in the hands of two rather distinct classes of workers. The engineers, on the one hand, have designed and built precipitators (or treaters, as they are called) and have changed and improved these from time to time so that the modern installation is a very different structure from the earlier ones. The physicists and laboratory investigators, on the other hand, have been more concerned with the fundamental principles involved in the phenomena of precipitation, such as the characteristics of the electrical field in a precipitator and the factors which govern the actual rate of precipitation.

Of these two groups, the engineers have made much the better progress. In fact, it can probably be said without injustice that with but few exceptions all the development in the art that has taken place has until recently been due solely to the engineers. This discussion, however, will be more concerned with the physicists' and investigators' side, and the report of the engineering development that has been done in these years will be reserved for a separate paper.

Types of Treaters in Use

Considering the length of time that has been available for investigation, and particularly the many opportunities for research of a fundamental nature, the progress that has been made has not been very rapid. Take, for example, the type of precipitators that are now used. These types are, of course, based primarily on the fundamental principles involved, and any great advance in this field of knowledge would necessarily be reflected in the apparatus erected for the commercial embodiment of the process. The only types in commercial use today are the so-called plate, pipe and transverse screen treaters, the name in each case being derived from the kind of collecting electrode used. Of these three, the first two were used in the very beginning of the commercial development and the last was described by Dr. Cottrell in his early patent specifications.

Nor have there been until recently many advances in the theory of the process. Most physicists who have investigated the problem have based their theories on the well-known laws of the conduction of electricity through gases, and have assumed that the forces acting in an electrical precipitator are not much different from those that would come into play if an externally charged particle were placed in an electric field. Aside from some improved methods of determining the mobility of such charged particles and some refinements in calculating the strength of the electric field, the latter attempts to explain the process differ little from the earlier ones.

Perhaps the chief reason for this lack of progress has been the difficulty of doing quantitative experimental work on a laboratory scale. For example, practically all such work necessitates a source of fume- or dust-laden gases of controllable characteristics, and this in itself is a difficult problem. Furthermore, the characteristics of the electrical field are very often entirely dissimilar in a small laboratory precipitator from those obtaining in a large installation, even when care is taken to maintain comparable conditions. As a consequence, it has seldom been possible to duplicate field conditions in laboratory investigations or to duplicate laboratory results in actual field operation. Moreover, the ordinary electrical precipitator is not amenable to modifications for experimental purposes, so that field experimentation has been difficult.

Essentials of Electrical Precipitation

Considered superficially, electrical precipitation of suspended particles from gases is very simple. The ordinary precipitator is merely an arrangement of two electrodes of the point to plate type, with a unidirectional potential difference established between them, of sufficient magnitude to cause ionization of the gas at the point, or discharge electrode. The ions thus formed are forced over to the plate or collecting electrode by the electric field, and if any solid particles are present in the gas and pick up any ions, they will also be forced over to the collecting electrode. However, while any such arrangement, or in fact any arrangement whatever consisting of two opposing electrodes in the gas, will precipitate a certain proportion of the suspended particles, the rate of precipitation in many cases is too slow for practical consideration.

A full knowledge of the law governing this rate of precipitation is, of course, absolutely essential for satisfactory progress in the art, and most of the investigations that have been carried on in this field have been concerned with factors pertaining thereto.

Back Ionization

As has already been indicated, there have been many discrepancies between the results of most of the investigations and actual practice. One of the most important causes of these discrepancies has been the phenomenon which has been called "back ionization." It was discovered early in the application of the process that often with certain types of fume quite irregular and unsatisfactory operation resulted from no apparent causes, the usual manifestation being a considerable loss in efficiency and increase in power consumption. It was also discovered that the operation could often be greatly improved by the addition of water vapor to the gases. The real nature of the disturbance was unknown, however, until E. R. Wolcott of this laboratory conducted

an extended investigation in this field. He showed (*Phys. Rev.*, N. S., vol. 12, 1918) that the cause of the disturbance in most cases lay in the non-conducting nature of the deposit. Thus when a non-conducting material is placed on the plate in a point to plate electric field, ionization takes place at the plate near the edges of the dielectric, while otherwise the ions are formed only at the point. Ions of the opposite sign to that of the point are thus introduced into the space between the electrodes, and these not only lower the maximum voltage of operation but also undoubtedly neutralize the effect of some of the ions of the opposite sign which would otherwise take active part in the precipitation.

Non-Conducting Surfaces on Electrodes

One can readily see how this effect is brought about. It is well known that ionization can take place only where the potential gradient exceeds a certain fixed value for each particular gas, and that with electrodes of varying curvature this gradient will be greatest at places of maximum curvature, as at the point in a point to plate arrangement. If now the plate be covered except in isolated spots by another dielectric as, for example, by an insulating powder, or by a sheet of mica having a few holes, the plate itself becomes equivalent to points at such places where it is not covered, the only difference being that at the point the dielectric is entirely air, while at the plate the dielectric is primarily some solid material. The potential gradient can, therefore, become sufficiently high, even at the plate, to cause ionization, and the electrode arrangement then becomes one of a system of points, instead of point to plate. Consequently, while there still may be a unidirectional current flowing, the ions will no longer be substantially of one kind traveling in one direction, but will be of two kinds traveling in opposite directions, so that ions coming from the point may be partly or wholly neutralized by those coming from the plate.

Then, too, the maximum voltage which can be maintained at ordinary pressures and distances is much lower when the point is positive than when it is negative, so that anything which tends to modify the plate, when it is positive, into a point or multiplicity of points greatly lowers this maximum voltage.

Function of Water Vapor

The obvious remedy for this condition when brought about by a deposit of fume on the plate electrode is, of course, to make this deposit conducting. This can be done in many ways, but the easiest way is to introduce moisture. It then becomes a question whether or not the material precipitated absorbs or adsorbs water vapor at the working temperatures so as to become conducting. In this respect there are great variations as, for example, from hygroscopic materials which *absorb* water readily, to substances like glass which *adsorb* moisture and become conducting when in the presence of water vapor of sufficient concentration, or substances like sulphur or silica which remain non-conducting even in the presence of fairly high concentrations of water vapor.

In most cases of actual practice, the desired conductivity of the deposits can be reached either by maintaining the temperature at the collecting electrodes so low that the relative humidity near the deposit becomes sufficiently high due to the water vapor naturally occurring in the gases, or by adding water in the form of spray or steam directly to the gases. In other cases the collecting electrode itself is covered with a film of water, which is then used as a carrier for the precipitated material.

Electrode Size vs. Rate of Precipitation

With this disturbing element understood and capable of being controlled, it has been possible to make better progress in the determination of the factors governing the rate of precipitation. Engineers of this company are just completing a lengthy investigation in this field. This investigation has to do largely with the relation between the size of the electrodes and the precipitation rate. The fume in this case was a soluble potash salt, carried by gases that were saturated with water vapor, so that the actual particles which were precipitated were particles of solution. Consequently the deposit was not only conducting but the electrodes were also self-cleaning, since the collected solution flowed off as soon as it was precipitated.

As a result of these experiments it is now possible to calculate and predict the gas volume, capacities and precipitation efficiencies of treaters or precipitators with much greater accuracy and certainty than has hitherto been possible. Furthermore, the design of such a precipitator can now be made on a sounder economical basis. For example, where the chief reason for installing precipitators is to save the values carried by the gases, it obviously makes a big difference in the design of the treater whether the material in the gases is, say, cement dust, worth perhaps $1 per ton, or lead fumes the value of which may be $50 per ton or more. In the former case it would naturally not pay to construct a very expensive precipitator with high efficiency, while in the latter case such a precipitator could economically be built. In both cases the aim should necessarily be to build such a treater that the net profit on the collected material, after deducting interest on the first cost, depreciation and operating expenses, will be a maximum.

Rational Design of Treaters

W. A. Schmidt of this company has developed a formula, based on the results of the investigation above referred to, by the use of which it is now possible to design and build precipitation installations on this really economical and logical engineering basis. This equation is of the form

$$x = a\left(\frac{\log \frac{b}{c \log d}}{\log d}\right)$$

In this equation a is the gas volume to be treated, b is a function of the unit cost of the precipitator, the rate of interest and depreciation and the cost of labor and power. The value of the solids carried by the gases is represented by c, d is a function of the specific precipitation rate for the fume or dust considered and x is the optimum size of the precipitator.

In this expression everything except x can be determined. Thus the gas volume to be handled, together with the amount and nature of the suspended solids, is always determined before any estimates are made. The potential value of all of the suspended matter can then be computed. The cost of labor and power, as well as the unit cost of construction, is ordinarily known from previous installations, and the constant d is either known from similar installations or preliminary tests can be made for its determination.

The development of such an equation represents a

distinct advance over the former methods of design where the estimates could only roughly be based on some former installations with whatever reservations the designer's ordinary judgment considered necessary. Of course, there is still much to be learned. The factors which influence the power consumption are not well known, nor has any satisfactory quantitative relation been determined between the rate of precipitation and the treater potential. Then there is the quantitative effect of the physical nature of each particular fume. In many of these cases sufficient data have been accumulated to express the relations graphically, but until a satisfactory analytical expression can be derived the problem cannot be considered as solved.

The accompanying table indicates the nature of the agreement between calculated and observed values for the precipitation efficiency, as based on the result of the recent investigations.

Type of Treater	Character of Fume	Gas Volume, Cu.Ft. per Min.	Efficiency — Observed, Per Cent	Efficiency — Calculated, Per Cent
Pipe	Potash fume	23,000	86	86
Plate	Potash fume	18,000	75	71
Pipe	Cement dust	150,000	94	92
Pipe	Metallic chloride	15,000	97	98.8
Pipe	Lead fume	102,000	82	85
Pipe	Bismuth fume	5,000	90	92
Transverse screen	Potash fume	1,000	73	75

Considering the wide variation in both the character of fume and the gas volumes handled, the agreement is encouraging and justifies the expectation of still further advances in the many other directions still under investigation.

Copper, Lead and Zinc Production in the U. S. for 1921

THE smelter production of copper in 1921 from ore mined in the United States, as shown by the actual production for the first 11 months and by estimates made by smelting companies for December, was about 461,000,000 lb., according to a report by H. A. C. Jenison of the U. S. Geological Survey. The refinery production as similarly shown was about 601,000,000 lb. from domestic material and about 320,000,000 lb. from foreign material.

According to the records of the Department of Commerce the total imports of copper for the first 11 months of the year in ore, concentrates, matte, blister and refined copper were about 318,000,000 lb., of which about 68,000,000 lb. was refined copper and 157,000,000 lb. was blister copper. The exports for the first 11 months totaled about 567,000,000 lb., of which about 538,000,000 lb. was new refined copper and 29,000,000 lb. was manufactured—wire, rods, pipes, tubes, sheets, etc.

The quantity of primary refined copper withdrawn on domestic account during the year was about 572,000,000 lb., calculated as follows:

	1920	1921
Refinery production from domestic courses	1,182,000,000	601,000,000
Refinery production from foreign sources	344,000,000	320,000,000
Imports of refined copper	109,000,000	75,000,000
Stocks of new refined copper Jan. 1	631,000,000	659,000,000
Total available supply	2,266,000,000	1,655,000,000
Exports (exclusive of manufactured copper)	553,000,000	587,000,000
Stocks on hand Dec. 31	659,000,000	496,000,000
	1,212,000,000	1,083,000,000
Total withdrawn on domestic account	1,054,000,000	572,000,000

The mine and smelter output of lead in the United States in 1921 each fell off about 20 per cent from the 1920 figures.

The output of soft lead by mines of the Mississippi Valley was about 231,000 short tons, and that of argentiferous lead by mines of the Western States was about 170,000 tons, a total of 401,000 tons. The corresponding figures for 1920 are 251,816 tons from the Mississippi Valley (including the small output of the Eastern States) and 259,070 tons from the Western States. The imports of lead in ore were about 7,000 tons, furnished chiefly by Canada, Mexico and South America, and those of lead in bullion were about 41,000 tons, almost wholly from Mexico, as compared with a total of 62,796 tons in 1920.

The output of primary domestic desilverized lead in 1921 was about 190,000 short tons, of soft lead about 145,000 tons and of desilverized soft lead about 55,000 tons, making a total output from domestic ores of about 390,000 tons of refined lead, as compared with 476,849 tons in 1920, which was made up of 220,327 tons of desilverized lead, 189,854 tons of soft lead, and 66,668 tons of desilverized soft lead. The output of lead smelted and refined from foreign ore and bullion was about 50,000 tons, as compared with 52,808 tons in 1920. The total lead smelted or refined in the United States was thus about 440,000 tons, as compared with 529,657 tons in 1920.

Zinc Production Decreases

The mine and smelter output of zinc each declined 60 per cent from last year's figures.

The recoverable zinc content of ore mined in 1920 was about 250,000 tons, as compared with 584,772 tons in 1920. The output of the Eastern States was about 68,000 tons, that of the Central States about 168,000 tons, and that of the Western States about 14,000 tons, as compared with 102,242, 337,652 and 144,878 tons respectively in 1920.

The imports of zinc in ore decreased from 22,487 tons in 1920 to about 2,700 tons in 1921, most of which was imported from Mexico.

The output of primary metallic zinc from domestic ores in 1921 was about 194,000 tons and from foreign ores about 2,500 tons, a total of 196,500 tons, as compared with 450,045 tons from domestic ores and 13,332 tons from foreign ores, a total of 463,377 tons, in 1920. In addition to primary zinc there was an output of about 17,000 tons of redistilled secondary zinc, as compared with 21,371 tons in 1920, making a total supply of distilled zinc and electrolytic zinc in 1921 of 213,500 tons, of which 31,500 tons was high grade and intermediate, 32,000 tons select and brass special and 150,000 tons prime Western. The output of the corresponding grades in 1920 was 114,606, 59,811 and 310,331 tons, respectively, a total of 484,748 tons.

Imports and Exports of Zinc

The imports of foreign slab zinc amounted to 6,674 tons, as compared with 15 tons in 1920. The exports of zinc made from foreign ores were about 1,260 tons and those of zinc made from domestic ores were about 3,200 tons, as compared with exports of 28,368 and 85,898 tons, respectively, in 1920. The exports of domestic zinc included about 1,800 tons of sheet zinc, as against 11,852 tons in 1920.

The two largest zinc-rolling mills have added zinc shingle machinery to their equipment. This use of sheet zinc is one of the most promising now being developed.

Brittleness Developed in Aluminum and Duralumin by Stress and Corrosion

Aluminum Is Deeply Corroded Where Impurities Lodge Between Primary Grains, but, if Recrystallized, Is Not Embrittled—Duralumin Is Subject to True Intercrystalline Embrittlement, Starting From Unknown Causes, but Intensified by Corrosion and Stress

By HENRY S. RAWDON, ALEXANDER I. KRYNITSKY and JULIUS F. T. BERLINER*

LE CHATELIER[1] has published a description of drinking flasks stamped out of sheet aluminum which disintegrated in service by intercrystalline crumbling of the metal. The material, which had a copper content of 3 per cent, cannot be properly designated as "aluminum." By electrolysis in a solution of sodium chloride, it was stated, the aluminum grains were dissolved, leaving unattacked the envelope of the copper aluminum compound ($CuAl_2$) which surrounded them. Seligman and Williams[2] have stated that they were unable experimentally to confirm Le Chatelier's observations, although they found that corrosion of overheated sheet aluminum and of the cast metal by dilute sulphuric acid produced somewhat the same effect.

Specimens of metal used as pyrometric standards[3] were used in some tests at the Bureau of Standards to determine whether pure aluminum behaved like lead when exposed to combined stress and corrosion.

Chemical analysis of the material gave: Fe, 0.18 per cent; Si, 0.15; Cu, 0.004; Mn, trace; C, 0.01; Co and Ni, not detected, and Al (by difference), 99.66.

Disks, 0.3 in. thick, were cut from a cylinder of cast aluminum, rolled to sheets 0.1 in. thick, and after being cut to size for the test and ground on the surface were annealed in order to remove the effect of cold-working and also to cause recrystallization and grain growth. The specimens used were of the approximate dimensions 4 x 1.9 x 0.15 cm.

As corroding liquids normal solutions of aluminum sulphate and of aluminum chloride were used, together with the same solutions after the addition of the corresponding acid. The results obtained for the two types of corroding solutions were very similar, so that only the results produced by the sulphate series are given in Table I. Corrosion was permitted to proceed for a period of 109 days at room temperature, which varied between 15 and 29 deg. C.

TABLE I. CORROSION OF PURE ALUMINUM

Spec. No.	Dimensions, Cm.	Area, Sq.Cm.	Corroding Solution	Loss of Wt. After 109 Days, Mg.	Loss per Sq.Cm per Day, Mg.
1	0.156x1.91x4.07	17.35	*N* aluminum sulphate	132	0.07
2	0.154x1.78x3.94	15.80	*N* aluminum sulphate + *N*/4 sulphuric acid	170	0.099
3	0.152x1.83x3.91	16.04	*N* aluminum sulphate + *N*/2 sulphuric acid	249	0.14
4	0.154x1.78x3.76	15.11	*N* aluminum sulphate + *N* sulphuric acid	320	0.19
5	1.56x1.91x3.94	16.92	*N* auminum sulphate + 2*N* sulphuric acid	520	0.28

The appearance of the plates after the corrosive attack is, however, more instructive as to the real character of the attack than is its numerical measure in terms of the loss of weight. From Fig. 1, which shows the characteristic appearance of the aluminum plates after corrosion, it is clear that the attack is not uniform over the entire surface. The definite etch-pattern which resulted suggests that the attack of the metal was intercrystalline in character. However, the crystals of the metal are very much smaller than the meshes of the network pattern which the corrosive attack revealed.

The examination of the corroded specimens after grinding off sufficient metal from the surface so that only traces of the etched pattern remained made it evident that the corrosion had been directed by the presence of certain constituents within the metal. These are shown in Figs. 2 to 4 to be without doubt the micro-constituents which existed as films enveloping the crystals in the cast metal and which are the result of the contaminating elements which the aluminum contained, principally iron and silicon. Although the position of these impurities may be changed somewhat by the distortion of the metal when the alloy is cold-worked, subsequent heat-treatment, short of melting, has no effect upon their distribution, so that a rough record of crystalline structure of the cast metal may be thus preserved in the annealed sheet by the location of these constituents. These impurities so accelerated the attack of the metal adjacent to them that the corrosive pattern produced constituted a record of the previous crystallization rather than that existing in the annealed sheet.

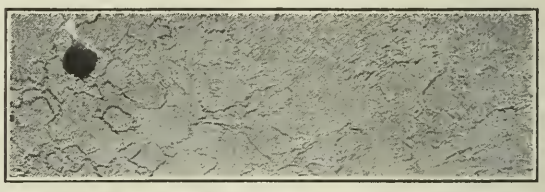

FIG. 1. ANNEALED ALUMINUM SHEET 4 AFTER 109 DAYS IMMERSION. × 1

The corroded strips were tested for intercrystalline brittleness by bending them sharply. However, no decided evidence of intercrystalline brittleness such as was reported for lead[4] was obtained. The surface network pattern appeared to be made up of wide and relatively shallow ditches rather than of narrow and deeply penetrating fissures. If the metal contains a higher percentage of impurities than the material used so

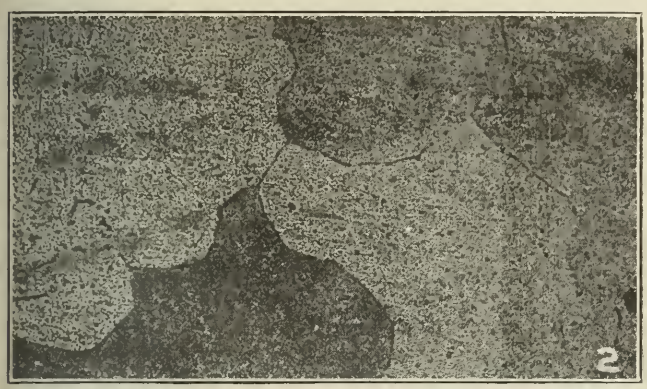
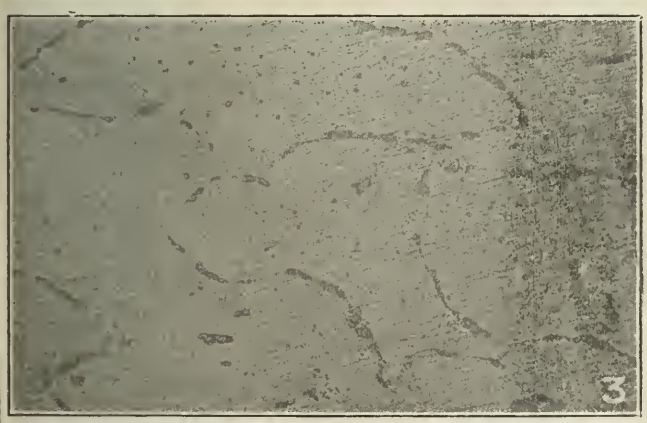
that the amount of the network constituent is considerably augmented, or if the sheet metal is overheated so that a large crystal size results and the impurities become somewhat intercrystalline in respect to their location, as the grains of the annealed metal approach the size of those formerly existing in the cast metal "intercrystalline" brittleness would be much more likely to occur as a result of a corrosive attack than was the case with the material tested.

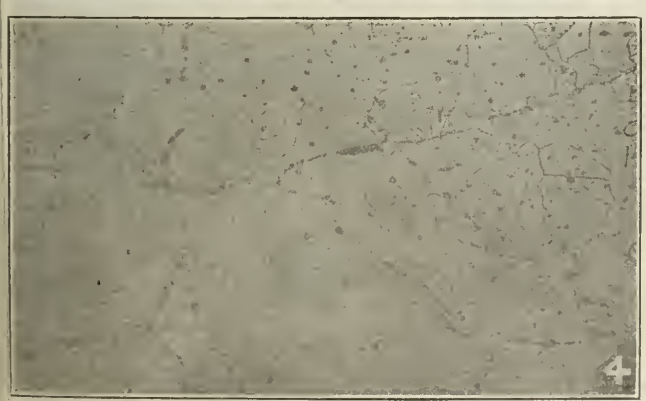
Embrittlement Under Service Conditions

A striking illustration of service deterioration of an aluminum alloy by intercrystalline brittleness was afforded by the examination of some sheet duralumin used as covering material in the elevator of an "all-metal" airplane. The two covering sheets, upper and lower, 0.012 in. in thickness, were of the corrugated type and fastened to each other by aluminum rivets along the edge and also to the duralumin tubes inserted between the sheets. A protective lacquer had been applied to both surfaces of the material. Most of the deterioration was localized near the riveted edge of the sheet and, in general, was confined to only one of the sheets; this happened to be the upper one. Portions of the sheet which were embrittled to the extent shown in Fig. 5 were in contact with apparently unchanged material of the other sheet.

FIG. 5. APPEARANCE OF THE EDGE OF A DURALUMIN SHEET WHICH BECAME EMBRITTLED IN SERVICE AS AIRPLANE COVERING. × 1







FIGS. 2 TO 4. RELATION OF THE CORROSION PATTERN PRODUCED ON THE SURFACE OF ALUMINUM SHEETS TO THE MICROSTRUCTURE OF THE METAL. × 75

Fig. 2—Cast aluminum. Fig. 3—Same material after reducing in thickness in the ratio 5 : 1 by cold rolling. Fig. 4—Material of Fig. 3 after annealing so as to cause recrystallization and grain growth. Etching reagent, 8 per cent hydrofluoric acid followed by an immersion in concentrated nitric acid.

When received, a brown deposit was found in spots on the surface of the embrittled sheet, and the surface, after cleaning, had the appearance of having been corroded in such spots, as shown in Fig. 5. The metal was most severely embrittled in the white spots. The characteristic appearance of the deteriorated sheet, as revealed by slightly etching the surface, is shown in Fig. 6. The intercrystalline nature of the attack by which the metal was embrittled is very evident, and the microscopic examination of cross-sections of the sheet demonstrates beyond question that the attack was of this nature. Fig. 7 shows the embrittled sheet without etching; several deep cracks are noted which become jointed together in a network on etching (Fig. 8). Deep corrosion produces the etching pits of Fig. 9, which demonstrate beyond question that the fissures which caused the embrittlement are intercrystalline.

The results of the chemical analysis[5] of the two sheets are given in Table II. The sheet which was most severely embrittled has been designated as *B*, the other one as *A*.

TABLE II. COMPOSITION OF DURALUMIN SHEETS WHICH DETERIORATED IN SERVICE

Element Determined	Bottom Sheet *A*, per Cent	Top Sheet *B*, Most Severely Embrittled, per Cent
Copper	3.40	3.56
Silicon	0.19	0.38
Iron	0.36	0.40
Manganese	0.21	0.29
Magnesium	0.54	0.57
(Lead, nickel and zinc)	Not detected	Not detected
Aluminum	95.30	94.80

The two sheets were of essentially the same composition and the results of the chemical analysis suggested no explanation as to the unusual behavior of some of the material in service. The percentage composition of each

[5]The authors are indebted to J. E. Scherrer, associate chemist, Bureau of Standards, for the analysis given here.

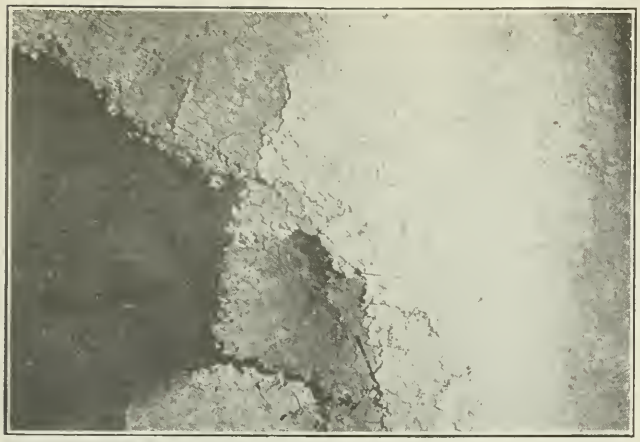


FIG. 6. PORTION OF SPECIMEN SHOWN IN FIG 5, SLIGHTLY ETCHED WITH 10 PER CENT NaOH FOLLOWED BY 8 PER CENT HF. × 5

of the sheets falls within the usual limits for duralumin.[6]

The mechanical properties[7] of the two sheets as determined by a tension test of portions which appeared to be sound are summarized in Table III.

Both sheets are inferior in their tensile properties to what may be developed in this alloy by proper treatment. The results of the test do not suggest that the material was given any special treatment for improvement of its mechanical properties. The ductility of sheet *B*, which deteriorated in service, was found to be distinctly lower than sheet *A*. The most probable explanation for this is that deterioration (intercrystalline embrittlement) had occurred over the surface of the sheet to an appreciable extent. The effect of such an attack of the surface would be to produce numerous microscopic "notches" in the "skin" of the sheet, a feature which would affect the ductility of sheet to a greater degree than the other tensile properties.

TABLE III. TENSILE PROPERTIES OF THE DURALUMIN SHEETS EXAMINED

Sheet	Orientation of Specimen	Width of Specimen, In.	Cross-Sectional Area, Sq.In.	Yield Point, Lb./Sq.In.	Ultimate Tensile Strength, Lb./Sq.In.	Elongation in 2 In., per Cent
A (bottom sheet)	Longitudinal	0.782	0.00954	20,500	34,100	8.0
		0.785	0.00958	20,900	35,500	9.5
B (top sheet)...	Longitudinal	0.774	0.00944	21,200	30,200	4.0
		0.783	0.00955	18,300	24,100	2.0
A (bottom sheet)	Transverse..	0.765	0.00933	24,100	39,500	6.0
		0.760	0.00927	22,100	37,700	5.0
B (top sheet)...	Transverse..	0.763	0.00931	26,900	45,100	5.5
		0.764	0.00932	26,900	40,600	1.0
		0.740	0.00903	25,500	30,500	1.5

[6]Bureau of Standards Circular 76, "Aluminum and Its Light Alloys."

[7]The mechanical testing of the material was done by S. N. Petrenko, associate engineer physicist, Bureau of Standards.

Attempts to Induce Brittleness

The fact that corrosion is of prime importance in producing the embrittlement of the sheet was readily demonstrated by means of a series of corrosion tests. Transverse strips representative of both sheets were cut from the portions which were still ductile and immersed in the following solutions: (1) *N*/20 aqueous sodium hydroxide; (2) *N* aqueous aluminum sulphate; (3) *N* aqueous aluminum sulphate containing *N*/10 sulphuric acid; (5) *N* aqueous aluminum sulphate with *N*/5 acid. Strips ¼ x 1½ in. were used. Some of these were bent into an arc of a circle with a radius of approximately 1 in. and held in this position by means of a thread tied at each end of the strip. The material was not permanently bent out of shape by a distortion of this amount. Other specimens were immersed in the unstressed or flat condition. It was expected that if intercrystalline embrittlement occurred as a result of corrosion, the network of fine cracks would develop "spontaneously" in those specimens which were corroded while under stress, whereas in the flat unstressed strips such "embrittlement cracks" would become apparent only upon sharply bending the corroded specimen.

The action of sodium hydroxide upon aluminum is a vigorous one even with solutions as dilute as N/20 and it was soon evident that embrittlement of the alloy would not result as a consequence of alkaline corrosion of this kind. The surface of the metal was attacked rather uniformly and at a rapid rate so that the strips became very thin and were covered by a closely adhering black coating. Sharp bending of the corroded speci-

men after removal of the coating revealed no trace of an intercrystalline attack such as developed in service in sheet *B*.

The three other solutions closely resembled one another with respect to their corrosion of the specimens immersed in them. The intensity of the attack was approximately proportional to the acidity of the solution. All of the specimens became coated with a black deposit which became brown after standing several weeks in the solution, undoubtedly by the oxidation of the copper which it contained. This deposit resembled, in appearance, that which was found upon the sheet which deteriorated in service. Fig. 10 is typical of the results obtained with sheet *B* in these solutions. It represents a portion of a 2-in. strip from the ductile part of sheet *B* immersed for 12 days in normal aluminum sulphate solution while simultaneously stressed by being bent into the form of a bow. It was then slightly bent to show the resulting damage. Fine intercrystalline cracks developed in the specimens in a relatively short time. Some of the stressed specimens developed cracks, revealed upon sharp bending, in the acidified solutions in 4 days, and in 12 days' time the

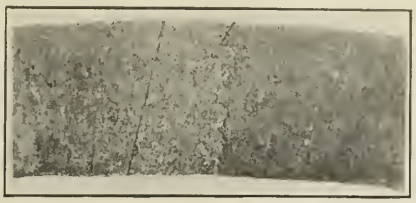

FIG. 10. SHEET *B*, DUCTILE PART, CRACKED UNDER STRESS AND CORROSION. × 4

cracks were evident in the stressed specimens in these solutions without bending and in the unstressed specimens upon bending. Some of the stressed specimens immersed in the neutral corroding solution (*N* aluminum sulphate) after an interval of 12 days showed cracks upon bending, but these were not pronounced until later. After an immersion period of 30 days all of the specimens cut from sheet *B*, in each of the three corroding solutions, showed well-developed intercrystalline network of "cracks."

The behavior of specimen *A* was quite different from that of *B*. After an immersion period of 55 days in each of the three solutions nothing suggestive of intercrystalline brittleness was found. Although in some cases, particularly in the acid solutions, the specimens became somewhat brittle as shown by the behavior upon bending the strip, the deterioration appeared to be caused by pitting rather than by an intercrystalline attack. As might be expected, however, the specimens of sheet *A*, immersed in *N*/20 sodium hydroxide solution, were attacked in a manner similar to that of sheet *B* in this solution.

Anneal Not Determining Factor

From a comparison of the microstructure of the two sheets (Figs. 11 and 13) it might be inferred that a difference in the annealing which the sheets received was mainly responsible for the difference in their behavior under corrosive conditions, although the tensile properties of the two sheets were not suggestive of any pronounced difference in this respect. Apparently the answer is not so simple as this. Specimens from the two sheets were annealed by us for 2 hours at 410 deg. C., but this did not change their relative behavior upon corrosion.

The theory of Rosenhain[5] that a metal or alloy in which the crystals have smooth rounded outlines is subject to intercrystalline changes, while the same metal or alloy in a different physical condition whereby deeply interlocking grains result does not seem to answer the question here. It is evident from Figs. 11 and 13 that there is a considerable difference in crystal size, but that the nature of the grain boundaries is not markedly different in the two cases, particularly if the difference in grain size is taken into account.

In general, the results of the tests indicated that a corrosive attack, particularly an acid solution, is a powerful aid in producing intercrystalline brittleness in certain types of duralumin sheet. The results do not warrant the conclusion, however, that corrosion of duralumin always manifests itself by an intercrystalline attack with an accompanying embrittlement of the

material. The physical state of the alloy and the character of the surface of the sheets appear to be factors of importance which determine the stability of the material when subject to corrosive conditions.

Summary

The nature of the attack in aluminum is determined largely by the amount and distribution of the microstructural constituents which are always present to some extent in commercial aluminum on account of the impurities contained. In the case of cast aluminum, these constituents are intercrystalline in their distribution, but not usually so after recrystallization and grain growth have taken place upon annealing after cold work. Annealed aluminum may, upon being corroded, appear to be attacked in an intercrystalline manner. Examination will often show, however, that the attack was not truly intercrystalline in its nature, but was determined by the presence of certain constituents which existed in the cast metal as intercrystalline lodgments but which, because of a subsequent recrystallization of the metal, no longer coincide with the network of crystal boundaries existing in the annealed metal.

The alloy of aluminum, duralumin, in the form of sheets is subject to a type of deterioration which is truly intercrystalline in character. The rate at which such deterioration progresses can be very much increased by the action of a corroding medium, but the evidence available did not warrant the conclusion that corrosion alone can initiate such deterioration, nor was it evident that the distribution of impurities or microstructural constituents was entirely responsible.

Life Tests of Platinum:Platinum-Rhodium Thermocouples

By C. O. Fairchild and H. M. Schmitt

FOR many years the so-called Le Chatelier thermocouple, consisting of one element of platinum and the other of an alloy of 90 per cent platinum and 10 per cent rhodium, has been known to be the best type of thermocouple for use at temperatures in the range 1,000 to 1,600 deg. C. No other metals or alloys have been found to compare favorably with this combination. The couple does, however, deteriorate quite rapidly when used at high temperatures, and requires frequent replacement or recalibration. The reasons for this have never been thoroughly investigated. Experimenters and other users of thermocouples have frequently observed that thermocouples obtained from different makers or even from the same source do not always exhibit the same rate of deterioration—i.e., time-rate of change of emf.—at any particular temperature. It has been supposed that the couple was particularly sensitive to the slightest contamination and that the variations in rate of deterioration depended primarily upon this fact.

Our attention was first brought to the problem of identifying the causes of the changes in thermocouples by a request addressed to the Bureau of Standards to test the relative efficiency of different types of porcelain protection tubes for thermocouples. Such tests have been deferred until couples can be obtained which are sufficiently free from deterioration under laboratory conditions. The experiments have shown that few thermocouples now in the possession of the Bureau of Standards will withstand exposure to high temperatures sufficiently well to offer exact means of determining the relative efficiency of different modes of protection.

Thermocouples to be tested were loaned to the Bureau of Standards by manufacturers, with the understanding that the results of the tests would be available for publication by this bureau. There are only two distinct makes of rare-metal couples now on the American market, one of American and the other of English manufacture.

The results of comparative tests, given below, are described for couples designated as American and English. The standard couple used is called *P*21.

Effects of Exposure to High Temperatures

The couples were first carefully calibrated by comparison with a laboratory standard numbered *P*21 used only for this purpose, and exposed to high temperatures for very short intervals only. The calibrations were made at a depth of immersion of 11 cm. The original values obtained follow:

ELECTROMOTIVE FORCE VS. TEMPERATURE, DEG. C.

Millivolts	*P*21 Deg. C.	American Deg. C.	English Deg. C.
2.00	267	269	264
3.00	375	377	369
4.00	478	480	467
5.00	578	580	559
6.00	674	677	646
7.00	767	771	730
8.00	858	862	811
9.00	946	950	889
10.00	1,032	1,036	965
11.00	1,116	1,120	1,039
12.00	1,199	1,203	1,111
13.00	1,281	1,285	1,181
14.00	1,363	1,367	1,250

After being heated for 18 hours at 1,250 deg. C. in a clean platinum-wound furnace at a depth of immersion of 11 cm. the couples were again compared with *P*21 at the same immersion, giving results as follows:

Thermocouple	Temperature Indicated, Deg. C.	Error In Pt, Deg. C.	Error In Alloy Deg. C.
*P*21	1,200	..	..
American	1,198	0	2
English	1,191	0	9

The couples were then heated as before for 6 hours at 1,450 deg. C. and again compared with *P*21:

Thermocouple	Temperature, Indicated, Deg. C.	Error In Pt, Deg. C.	Error In Alloy Deg. C.
*P*21	1,200	..	..
American	1,194	3	3
English	1,186	3	11

Since the effects observed cannot be attributed entirely to contamination in the furnace and must therefore be due in part to elimination of impurities by heating, it appeared desirable to accelerate the removal of impurities by use of a solvent. The following treatment was accordingly applied:

Each couple was heated, in air, at about 1,400 deg. C. by passing an electric current through it, and borax was applied which melted and washed the surface. The borax was then removed with hot hydrochloric acid and the couples electrically heated for 3 hours at 1,500 deg. C. Next the temperature was lowered to about 900 deg. C. and the couples were kept covered with borax applied at frequent intervals for 2 hours. The borax was then dissolved off as before and the couples were heated again for 30 minutes at 1,500 deg. C.

This borax treatment has been used for a number of years at the Bureau of Standards for improving contaminated couples and has been found very effective in rendering the couples more homogeneous. The follow

Published by permission of the Director, Bureau of Standards.

ing results were obtained by again comparing the couples with *P*21 at 11 cm. immersion:

Thermocouple	Temperature Indicated, Deg. C.	Error In Pt, Deg. C.	Error In Alloy, Deg. C.
*P*21	1,200	..	..
American	1,191	6	3
English	1,142	4	54

In order to indicate still more strikingly the difference in the metals, comparison with *P*21 was made with 6 cm. immersion:

Thermocouple	Temperature Indicated, Deg. C.	Error In Pt, Deg. C.	Error In Alloy, Deg. C.
*P*21	1,200	..	..
American	1,180	17	3
English	1,118	12	70

It would be expected that these couples should show greater changes when tested at 6 cm. immersion, after use at 11 cm. immersion, than when tested at 11 cm. immersion, since in the former position the region of thermo-electric heterogeneity developed by the previous heating is brought into a region of high temperature gradient. It is not evident, however, why the comparatively pure platinum wires of the couple should show a change as great as the equivalent of 17 deg. C.

In these last comparisons the combined effects of the heating and the borax treatment are apparent. To show the effect of the borax treatment alone, comparison with *P*21 was made at 14 cm. immersion:

Thermocouple	Temperature Indicated, Deg. C.	Error In Pt, Deg. C.	Error In Alloy, Deg. C.
*P*21	1,200	..	..
American	1,197	0	3
English	1,150	1	49

Spectroscopic tests were used to show what impurities were originally present in the metals. The analyses explain the effects described above. The platinum showed in each case traces of calcium. The alloys each showed traces of copper and calcium and the English alloy showed the presence of considerable iron. Chemical analysis resulted in finding iron to the extent of 0.34 per cent in this alloy.

Weight Loss by Volatilization at High Temperatures

Sections of wire carefully cleaned and heated momentarily to a red heat were carefully weighed and heated electrically in air as follows:

1. Temperature, 1,375 deg. C.; time, 30 min.

Material	Loss in Weight, G.
American Pt.	0.00016
English Pt.	0.00016

2. Temperature, 1,450 deg. C.; time, 30 min.

American alloy	0.00041
English alloy	0.00076

(*a*) Continued for 2 hr. at 1,450 deg. C.:

American alloy	0.000162
English alloy	0.000171

(*b*) Continued for 1 hr. at 1,600 deg. C.:

American alloy	0.000184
English alloy	0.000188

The action is mostly on the surface, such that repeated heatings show decreasing differences. The results are computed for loss per sq.cm. of surface.

The tests described are sufficiently complete for the purpose in mind. They indicate quite plainly that purity of the metals used in making rare-metal thermocouples is of primary importance and that a very high degree of purity is desirable. It is obvious that such impurities as were found, all of which volatilize or oxidize easily, are particularly objectionable.

The platinum has been found to be very good and to compare fairly well with the purest obtainable. No doubt there was some accidental contamination of the thermocouple, but it is not apparent that this could have materially affected the general conclusions concerning the alloy elements.

Conclusion

Tests of thermocouples obtainable on the American market have shown that considerable improvement is desirable, particularly in the English make. The fact that the manufacturers have been able for years to supply thermocouples closely reproducing their thermo-electric standards permits us to infer that the materials used in manufacture of the couples are the same now as they have been in the past. The usefulness of the couples in industrial applications has been proved, though the tests explain some of the faults which have been found during use in manufacturing plants.

The manufacturers of the thermocouples tested have been informed of the results enumerated and are now working to improve their product. The Bureau of Standards will probably repeat the tests in the near future, when better couples have been made.

The Pyrometry Section of this bureau has been aided materially in this work by Dr. E. Wichers of the Chemistry Division and Dr. W. F. Meggers of the Optical Division. Dr. Wichers and his assistants are making a special study of the platinum metals, and Dr. Meggers and assistants are engaged in research in spectroscopy, including its application for quantitative measurement of impurities in metals and alloys.

* * *

Later Tests on English Thermocouple

Subsequent to the completion of the tests reported in the preceding article, the manufacturer of the English rare-metal thermocouple submitted new material to the Bureau of Standards and an additional series of tests was made. It is significant to note that although in the previous tests the alloy wire of this make had been found to contain 0.34 per cent of iron, spectroscopic tests of the new alloy failed to show the presence of iron.

The tests made on the English thermocouple are not comparisons of the English and American makes, and since the conditions of the previous test could not be duplicated exactly, no attempt was made to follow the original procedure. This procedure was, however, adhered to closely enough to prove definitely whether or not the new thermocouples are better than the old thermocouples submitted by the English maker. The results obtained are highly satisfactory, as shown below.

The couples were first carefully calibrated by comparison with a laboratory standard numbered *B*1. The calibrations and all subsequent comparisons with the standard were made at a depth of immersion of 25 cm. The test couples are designated as *L* and *M*, the latter having an alloy of 90 per cent platinum and 10 per cent rhodium and the former 13 per cent rhodium. The original values obtained follow:

ELECTROMOTIVE FORCE VS. TEMPERATURE, DEG. C.

Millivolts	*B*1	*L*	*M*
2	265	260	265
3	374	363	374
4	478	459	477
5	578	551	577
6	675	639	674
7	769	724	768
8	861	806	859
9	950	886	948
10	1037	964	1034
11	1122	1040	1118
12	1206	1114	1201
13	1289	1186	1284
14	1372	1257	....

This calibration of couple *L* is different from that of

the couple submitted for the original tests, on account of the elimination of iron from the alloy. This difference will not seriously affect industrial applications, though it amounts to 15 deg. at the higher temperatures.[1]

Effect of Exposure to High Temperatures

After heating for 6 hours at 1,450 deg. C. in a clean platinum-wound furnace the couples were again compared with *B*1, giving results as follows:

Thermocouple	Temp. Indicated, Deg. C.	Error	
		In Pt, Deg. C.	In Alloy, Deg. C.
*B*1	1,200	...	...
L	1,199.7	0.5	0.8
M	1,199.4	0.2	0.8

The couples were then heated for 18 hours at about 1,600 deg. C. by passing an electric current directly through them suspended in air, and were again compared with the standard, *B*1:

Thermocouple	Temp. Indicated, Deg. C.	Error	
		In Pt, Deg. C.	In Alloy, Deg. C.
*B*1	1,200	...	...
L	1,198	0.7	2.7
M	1,202.3	2.0	0.3

One of the couples was then treated with melted borax as in the previous tests, giving the following results:

Thermocouple	Temp. Indicated, Deg. C.	Error	
		In Pt, Deg. C.	In Alloy, Deg. C.
*B*1	1,200	...	...
L	1,198	2.1	4.1

At the request of the maker a test in the platinum-wound furnace at 1,500 deg. C. was begun. At the end of 23 hours the couples were removed for comparing with *B*1, giving these values:

Thermocouple	Temp. Indicated, Deg. C.	Error	
		In Pt, Deg. C.	In Alloy, Deg. C.
*B*1	1,200	...	...
L	1,197	1.3	4.3
M	1,200.2	0.3	0.1

In order to determine if possible whether or not the couples were undergoing contamination, sections from near the hot junction of couple *L* were removed and tested spectroscopically. The only result of this test was the identification of rhodium in the platinum. The section removed was far enough from the hot junction to exclude the portion contaminated by welding the junction and to permit the conclusion that rhodium had been volatilized from the alloy and had contaminated the platinum. Apparently the 13 per cent alloy had lost rhodium appreciably faster than the 10 per cent alloy, and the tests were stopped at this point, because results of long continued exposure to the higher temperature would not indicate the quality of the wire, but would be confused with the change due to the transfer of rhodium.

Spectroscopic Analysis

Spectroscopic tests of the platinum and alloys were made which indicated that both metals were exceedingly pure, very minute traces of calcium and copper being found in each. Re-examination of the spectrograms made in the original tests resulted in finding traces of copper in all the platinum submitted.

The traces of impurities found in the platinum account for most of the changes observed in these tests, but the loss of rhodium from the alloy has prevented any conclusion from being drawn as to the effects of the impurities in the alloys. The Bureau of Standards has been studying the properties of pure platinum and it is now known that the impurities found cause variations in the thermo-electric properties of the metal to approximately the extent noted in these tests, and it is highly probable that such quantities of impurities can slightly affect the refractoriness of the alloy. However, the alloy of couple *M* remained remarkably homogeneous throughout the tests.

Conclusion

The original tests of the English and American makes of thermocouples revealed that the former deteriorated too rapidly when exposed to high temperatures; and the tests showed that this trouble was caused mainly by iron in the English make of alloy. The English maker has improved his products, and as a result rare-metal couples conforming to the high emf. standard can now be obtained, which will be satisfactory for use at high temperatures. The latter type of couple will now be known as a 13 per cent alloy couple. This 13 per cent alloy has a thermo-electric power against platinum of approximately 14 microvolts per degree at 1,200 deg. C., while the 10 per cent alloy gives but 12 microvolts per degree at this temperature. The tests indicate that the 10 per cent alloy is more refractory than the 13 per cent alloy, but, as shown above, a total change of only 4.3 deg. due to change in this alloy alone was found after the very severe treatment received.

For industrial use the rare-metal couples now obtainable are sufficiently refractory to direct attention once more to methods of and materials for protection. Adequate protection from furnace gases and vapors at 1,450 deg. C. and upward is still lacking. A more refractory porcelain is wanted and one which has been fired and vitrified at a temperature of not less than 1,550 deg. C.

Bureau of Standards,
Washington, D. C.

[1] See Bureau of Standards Tech. Paper 170 for mean calibration of a large number of couples of this type submitted to the bureau for testing.

National Safety Council Compiling Census of Safety Workers

The National Safety Council is undertaking the compilation of a census of all persons engaged in safety and industrial health activities. The chemical industry has, because of inherent hazards of its nature, always been among the leaders in industrial safety, but it has never been established definitely how many persons in the chemical industry are engaged in accident prevention and industrial health work, or how this industry compares with other industries in this respect.

Industry in general and the nation at large will profit from the results of this census. It will enable the Council quickly to find speakers on industrial and public safety for any occasion in any locality; authors for special articles on accident prevention; writers of safety textbooks; lecturers on accident prevention and industrial health work for universities and colleges. The Council at present continually receives requests from industrial companies, municipalities, civic associations, clubs, schools, colleges and other organizations for help in finding speakers or writers on safety subjects. The census records will greatly increase the facilities of the Council for filling such requests.

Every reader of this publication who is professionally engaged in industrial or public accident prevention or industrial health work—whether he is devoting all or only part of his time to accident prevention—is urged to assist in the taking of this census by sending his name to the National Safety Council, 168 North Michigan Ave., Chicago.

Explosives and Fertilizers*

A Broad Economic View of the World's Resources Indicates That Our National Defense, Our Future Food Supply and Our Continued Industrial Pre-eminence Depend on Nitrogen Fixation and the Maintenance of Chemically Trained Personnel

By ALFRED H. WHITE
Professor of Chemical Engineering, University of Michigan

THE intimate connection between explosives and fertilizers has been well known to the scientific world, but the roar of the stupendous explosion at Oppau in Germany a few months ago has perhaps accentuated it and has certainly brought vividly to the lay mind the possibility of the use of the same material for the two widely differing purposes. The mechanism of that unexpected explosion, which blotted out four hundred lives, is still a matter of conjecture, but it seems clear that a warehouse reported to contain 7,000 tons of a mixed salt of ammonium nitrate and sulphate, intended perfectly legitimately for fertilizer and believed to be entirely safe, unexpectedly exploded with all the violence of a high explosive.

The battle of Crecy has been famous for nearly 700 years, not so much because of the victory which the English won as because of the introduction of gunpowder and artillery as a decisive factor in warfare. It has been recognized for centuries that superiority in explosives and artillery was one of the strongest assets of a contending nation. As Napoleon cynically phrased it, "God is on the side of the heaviest artillery." Our own country has been hampered in all its major wars by lack of sufficient explosives. The Continental Congress urged the colonists in the days of the Revolution to make niter plantations to supply the nitrate needed for gunpowder. During the war of 1812, the earthen floors of Mammoth Cave in Kentucky were leached for the meager supply of nitrates stored therein. In the Civil War the armies of the North were not nearly so hard pressed as those of the South, but many of the battles came to a standstill through exhaustion of ammunition. We remember the desperate state of the British armies in Flanders in 1914 and 1915, when they were subjected to the withering fire of the German batteries without even the possibility of an effective reply.

The Allies' Demands for Explosives

When we entered the war, in 1917, the first demand made upon us was for explosives. This was emphasized in the meetings of the Interallied Council in the fall of 1917, when it was brought out that during the year 1918 Great Britain and France could supply artillery for all of our troops, as well as theirs, but that they were in desperate need of explosives for their own troops. They specifically requested "that the American efforts shall be immediately directed to the production of propellant and high-explosive powders on the largest possible scale." The reason for this shortage of explosives in France and Great Britain is found in the lack of raw materials in these countries. We think of smokeless powder as requiring cotton, nitric and sulphuric acids, and alcohol; and of the high explosives as requiring ammonium nitrate together with toluene, sulphuric and nitric acids, but the fact which escapes our attention is that the raw material whose tonnage is greatest is one that does not appear at all in the finished product. It is coal. Each pound of smokeless powder requires 9 to 10 lb. of coal. The French had to import from 8 to 12 tons of raw materials for each ton of high explosives, and from 15 to 20 tons of raw material for each ton of smokeless powder. The expenditure of explosives during the World War was on a scale undreamed of before that time. Our American artillery, in its preparation for the attack on the St. Mihiel sector, fired two-thirds as many rounds of ammunition in 4 hours as the Union forces fired in 4 years during the Civil War.

The response that we made to our allies' demand for explosives was a striking proof of the ability of this country to undertake large operations. Fortunately, most of the raw materials were present in abundance. Coal, cotton, alcohol and sulphuric acid were obtainable in ample quantity. The production of toluene had to be stimulated, but the process of manufacturing it from California petroleum, which was developed to meet the emergency, was capable of furnishing many times more than the needed amount. The greatest shortage of material was in fixed nitrogen, especially in the form of nitric acid. The main source of the world's nitrate was in Chile, separated by a long ocean voyage from this country and from Europe, and the submarine campaign called for the diversion of every possible ship to carry troops and supplies to France. There was no certainty whether it would be possible to maintain the shipment of the amounts of nitrate required, nor indeed whether Chile would remain neutral and willing to furnish us the raw material. Germany had foreseen that any war which involved Great Britain would immediately cut her off from supplies of nitrates, and she had guarded against this contingency, first by a large reserve stock, and second by the development of processes for fixation of the nitrogen from the air, which would render her independent of outside supply.

Nitrogen Preparedness—1914 and 1922

Germany's success in her nitrogen fixation program is a matter of common knowledge. She built plants which supplied her army with munitions and her soil with at least a part of its normal supply of fertilizer. No other country had deliberately planned for war, and so no other country had subsidized the development of this industry of nitrogen fixation. The ammonia from the coke ovens in the allied countries was entirely inadequate for the emergency, and England, France and the United States all worked feverishly to install

*A contribution to the Symposium on Chemical Engineering and National Defense presented before the Baltimore meeting of the American Institute of Chemical Engineers, Dec. 6, 1921.

fixation plants. These could not be built in a day and so the armistice came with the most of the plants uncompleted.

At the close of the war Germany had as assets her plants, whose construction cost had already been largely amortized. They have been merged into one immense combination with government assistance, so that they are in a position to act as a unit and expend their energies where they are needed. In our own country the unfinished plants were scrapped and only two were retained. U. S. Nitrate Plant No. 1, built to produce ammonia by direct synthesis of nitrogen and hydrogen under high pressures—a modification of the Haber process—was not entirely successful in its operation. U. S. Nitrate Plant No. 2, at Muscle Shoals, built to fix 41,000 tons of nitrogen a year by the cyanamide process, was a pronounced success. Both these plants are being maintained in a standby condition pending final decision by Congress as to their method of operation, if indeed they are to be operated at all. Other developments during and since the war have contributed to make our condition of nitrogen preparedness much better than it was in 1916. The stimulation in construction of byproduct coke ovens has doubled the amount of ammonia which may be produced in the United States from this source. Methods for oxidation of ammonia to nitric acid were developed during the war. Provided our country maintains a reasonable stock of nitrate of soda as a military reserve, these sources of ammonia production should permit us to supply the needful explosives for a defensive war. If, however, we were to be drawn into another such terrific cataclysm as that of 1914-1918, we would again be forced to construct new fixation plants.

Development of Nitrogen Fixation Processes

If we had to face another such emergency, we would be better prepared, for the processes of nitrogen fixation are much better known than they were when we entered the war. The cyanamide process had been well developed before the war both in Europe and at Niagara Falls, and the plant at Muscle Shoals, designed by the American Cyanamid Co., represents the most advanced construction in these lines. The other important process for nitrogen fixation, the Haber process and its variants, reached a high development in Germany during the war. The one plant attempted in this country and constructed with government funds at Sheffield, Ala., failed to operate satisfactorily. But the same private interests that designed this plant have, with the experience gained through the first venture, designed and constructed a plant at Syracuse, N. Y., which is said to be producing 12 tons of anhydrous ammonia per day and to be operating very smoothly and satisfactorily. In case it becomes necessary for the government to construct synthetic ammonia plants, there is a pilot plant with trained personnel, whose services would undoubtedly be made available to the government for the national defense.

From France comes the report that the famous French engineer M. Georges Claude has been successful in his daring attempt to produce ammonia synthetically, not at pressures of 100 atm., or even 250 atm., but at pressures of 1,000 atm. This process, which works with flammable gases in steel containers at red heat under pressures which are almost half of those set up in a cannon when fired, is certainly one of the most remarkable that has ever been attempted, and the success of M. Claude is further evidence that he is a chemical engineer of the very highest type.

It appears then that from the standpoint of raw materials for explosives our country is fairly well prepared for national defense. The one raw material which has been lacking, fixed nitrogen, is now provided in reasonable amounts from our coke ovens, with the government plant at Muscle Shoals as an immediate reserve and at least one private plant for direct synthesis of ammonia in successful operation.

Importance of Maintaining Trained Personnel

Raw materials are, however, only one of the things needed for explosives. Even more essential is the knowledge of manufacturing processes which exists only with the maintenance of a trained personnel. It is probable that commercial explosives will always be manufactured in this country, and it may therefore be argued that there will always be an adequate nucleus of personnel for war needs. But is it probable that the manufacturers of commercial explosives will be leaders in the development of new materials which might be used in warfare? What kind of explosives will be used in the next war? The only answer which we are warranted in giving at the present time is that they will be unstable chemical compounds which must be synthesized with very great care and will almost certainly be complex organic compounds. The one type of factor which is always working with this form of synthetic organic compounds is that which manufactures dyes.

The connection between the dye industry of the country and the manufacture of poison gases has been frequently discussed. The relation between the dye industry and explosives has not been emphasized so much, and yet the operations of nitration are fundamental both to the dye industry and to the manufacture of explosives, and certain materials such as picric acid and dinitrophenol are in themselves explosives as well as products of the dye manufacturer. The relation of explosives to poison gas is so very close that it is not possible to say with certainty where one begins and the other leaves off, and I cannot refrain from giving one specific instance of the ready adaptation of a dye works to the manufacture of poison gas.

Demonstrating the Impossibility of Chemical Disarmament

The Badische Anilin- und Soda-Fabrik of Germany has a capacity to produce 800,000 lb. of indigo each month. Its process starts with alcohol, which is converted into ethylene and then into ethylene chlorhydrin. This latter product is heated with aniline and the oily residue is fused with caustic potash; indigo is at once obtained from this fusion by solution in water and oxidation by air. Were Germany to be drawn into war this plant might be converted into a mustard gas plant in scarcely an hour's time. The first two steps in the process are identical; in the third step, sodium sulphide, a cheap chemical, is substituted for aniline and the solution thus obtained is concentrated and treated in large tanks with hydrochloric acid. The oily product settling out at the bottom is the well-known mustard gas, and may be drawn off at will.

This instance of the adaptation of a dye works to war purposes is cited partly to show the impossibility of chemical disarmament. Any nation which permits its dye industry to perish is in danger of destruction

by an enemy which is prepared to unmask these terrible agencies of destruction. These industries play an important part in our modern industrial organization, and unless the world is willing to do without colors and also synthetic medicinal products, these plants cannot be wiped out. The only safe protection appears to be in an equality of preparedness.

Preparedness for Peace

Let us turn our attention from preparedness for war to preparedness for peace—to the measures necessary to maintain the fertility of the soil. The importance of the subject has been well summed up by Theodore Roosevelt, who, writing in the *Outlook* in 1912, said:

> I have always been fond of history and of science, and what has occurred to Spain, to Palestine, to China and to North Africa from the destruction of natural resources is familiar to me. I have always been deeply impressed with Liebig's statement that it was the decrease of soil fertility, and not either peace or war, which was fundamental in bringing about the decay of nations. While unquestionably nations have been destroyed by other causes, I have become convinced that it was the destruction of the soil itself which was perhaps the most fatal of all causes.

One of our most eminent American agriculturists, he late Dr. C. G. Hopkins of the University of Illinois, howed in 1909 that one of their experimental fields vhich had been carried on crop rotation for 7 years vithout fertilization decreased in fertility so that the rop of corn fell from 57.3 bu. to 33.9 bu., and oats lecreased from 74.4 to 25.9 bu. per acre. A check plot ertilized by addition of nitrogen and phosphorus in- reased its yields of corn over that given in the earlier ears, and gave a crop of oats which, while not so large s in the first year of the test, was still 20 bu. greater han that given by the unfertilized plot.

The same authority cited the case of Russia, where he average annual yield of wheat for 20 years is 8½ u. to the acre and where a decrease of only 2 bu. to he acre means a famine. He gave the following solemn arning, which is strikingly similar in import to that of resident Roosevelt cited above:

> With the exception of a few small countries, the record of our race is a record of ruined lands; and if we repeat, in the great corn belt of America, the history of the white race in Palestine, in southern Europe, in Russia and in the eastern part of the United States, where shall our children go for bread?

We in the United States are accustomed to think of ır soil as a permanent asset, just as a generation go we considered our petroleum, natural gas and coal s permanent assets which did not need to be conserved. et the evidence is clear that even our richest soils e deteriorating. The State of Illinois is on the whole ıe of the richest farming states in this country, and t Dr. Hopkins has stated that if continuous crops of rn of 100 bu. per acre were grown on the Illinois farm nds, the supply of phosphate in the soil reached by ıe plow would be not diminished but totally exhausted from 51 to 105 years. A corn crop of 100 bu. quires for the grain alone 100 lb. of nitrogen. Some the poorer farm lands of Illinois contain only sufficient trogen in the surface soil for forty-six crops of this rt and none except the deep peat soils contain enough trogen in the surface soil to last more than 67 years. is recognized that phosphates and other mineral rtilizers in some form must be added to the soil if s fertility is to be maintained. The nitrogen problem . however, of more importance. The Illinois Agricultural Experiment Station states: "The nitrogen problem is the most important practical problem confronting the American farmer."

The Nitrogen Problem in Agriculture

Although there is agreement among agriculturists and scientists as to the seriousness of the nitrogen problem in agriculture, there is not the same unanimity as to the best means of maintaining the nitrogen content of the soil. The early Roman writers on agriculture knew the value of leguminous crops as restoratives of soil fertility. The system of maintenance of a permanent system of soil fertility by proper rotation of crops and utilization of plant residues forms the basis of the system advocated by Dr. Hopkins for Illinois soils. However, the system requires more than the usual care, for their bulletin states:

> The nitrogen of the soil, therefore, cannot be maintained simply by incorporating a legume in the rotation, as is too often assumed. The proper utilization of the legume hay produced, and the return of its nitrogen to the soil, is a problem of utmost practical importance.
>
> The use of a legume cover crop in wheat and oats also plays an important part in maintaining the nitrogen supply of the soil. The legume so used is probably of more importance really than its occurrence in the regular rotation.

It has been proved that the nitrogen content of soil such as that of Illinois can be maintained without addition of a commercial fertilizer, provided sufficient attention be paid to the biological processes. The question is not, however, decided for other types of soils and other methods of farming, and it is not settled whether the maintenance of the nitrogen content of soil through legumes is as economical as its partial restoration through commercial fertilizers. This is a question which can be answered only by a careful economic study and one which from its nature will have to be reconsidered with every variation in the cost items which enter the computation. The recent increase in the value of farm lands and in farm labor has made it necessary to recast pre-war figures.

Investigations made by the Farm Management Department of the Iowa State College of Agriculture, in co-operation with the Iowa Farm Bureau Federation in 1920, showed that the average direct cost of growing an acre of wheat in Iowa was $18.19, of which almost exactly 50 per cent was labor and less than 10 per cent was charged to fertilizer. It may be noted that this fertilizer was merely manure and undoubtedly entirely inadequate to replace the nitrogen lost in the crop. The point to be emphasized is that this typical acre which produced 18.5 bu. of wheat had expended upon it $18.19 as direct charges, to which was added the figure of $16.80 for land charges, so that according to the computation the total cost of wheat was nearly $1.90 per bushel. Almost one-half was a fixed charge due to the land.

Methods of Nitrogen Replacement

The Illinois system of permanent soil fertility as advocated by Dr. Hopkins dispenses with the use of commercial nitrogenous fertilizers, but gives no return at all to the owner of the soil during the fourth year, when the land is wholly given over to the cultivation of clover, which is to be plowed under and from which not even hay is to be cut. If the direct cost of caring for the land during this year is estimated at only $5 per acre and the land charge is to be $16.80 per acre, as

estimated in the Iowa figures given above, it will mean that the cost of this method for replacing the nitrogen in the soil is $21.80 per acre. If nitrogen in fixed form may be purchased by the farmer at 15 cents per lb., he could buy 145 lb. for this sum, and if nitrogen could be purchased by the farmer at 10 cents per lb., which is not at all an impossible figure, he could buy 218 lb. of nitrogen. This would provide for the nitrogen removed by 218 bu. of corn, so that theoretically the farmer could grow a heavy crop of grain every year and possibly be better off financially than if he kept up the nitrogen content of his soil wholly by clover or other leguminous crops. The advantage to the nation is evident, for the product of the land during every year, instead of only three years out of four, would add a potential one-third to our crop production.

The Chemical Engineer's Responsibility

It is not for the chemical engineer to decide what method of nitrogen replacement is best from the agricultural standpoint. It is proper for him, however, to consider how far he might meet a demand if it were made upon him.

The combined crops of wheat, oats and corn in the United States amount roughly to 5,000,000,000 bu. annually. Each bushel removes from the soil about 0.9 lb. of nitrogen, so that the total annual loss of nitrogen from the soil in the grains alone is 4,500,000,000 lb., or 2,250,000 tons, of nitrogen. This is not an exorbitantly high estimate. Dr. Lipman, director of the New Jersey Agricultural Experiment Station, was quoted in the hearings before the Senate Committee on Agriculture and Forestry (Senate Document 3,390) as having estimated that the total annual loss of nitrogen from all land under cultivation in the United States, after making allowance for all returns to the soil, was between three and four million tons.

These figures are staggering, but the authority is good. Let us assume that we must return to the soil through commercial fertilizers, not the larger figure of 4,000,000 tons, but the smaller figure of 2,250,000 tons representing the loss in the grains alone. The tankage, cottonseed meal and other organic compounds now used account for only 4 per cent of this amount and their total is decreasing rapidly. The coke ovens and private plants for nitrogen fixation in the United States would make up less than 5 per cent. Imports of Chilean nitrate in the same amount as used for fertilizer before the war would furnish only 2 per cent. There is lack of agreement as to the future life of these Chilean nitrate deposits, just as there is lack of agreement as to the number of years before our petroleum resources in the United States will be exhausted. There is, however, general agreement that the life of both resources is limited and that within one generation, or at most two generations, substitutes will have to be sought for the large uses of both these materials.

The organic wastes, coke-oven ammonia and Chilean nitrates might together account for perhaps 11 per cent of the 2,250,000 tons of nitrogen called for annually to replace that removed from the soil by the grain crops. The remaining 2,000,000 tons would have to come from fixation processes.

There is only one really large fixation plant in the United States—that owned by the Government at Muscle Shoals. It has a capacity for fixing 41,000 tons of nitrogen per year, but it would require forty-nine such plants to provide the nitrogen called for. Nitrogen fixation on this tremendous scale at a price which will render the product available for fertilizer is entirely impossible with our present technical developments. But is the prospect of such a demand merely a wild dream?

It was Sir William Crookes who twenty-three years ago, in his presidential address before the British Association for the Advancement of Science, first called the world's attention to the probable exhaustion of the nitrogen of the soil throughout the world. I quote from his address:

> Gradually all the wheat-bearing land on the globe is appropriated to wheat growing, until we are within measurable distance of using the last available acre. We must then rely on nitrogenous manures to increase the fertility of the land under wheat, so as to raise the yield from the world's low average, 12.7 bu. per acre, to a higher average. To do this efficiently and feed the bread eaters for a few years will exhaust all the available store of nitrate of soda. For years past we have been spending fixed nitrogen at a culpably extravagant rate, heedless of the fact that it is fixed with extreme slowness and difficulty, while its liberation in the free state takes place always with rapidity and sometimes with explosive violence. . . . The fixation of nitrogen is vital to the progress of civilized humanity. Other discoveries minister to our increased intellectual comfort, luxury or convenience; they serve to make life easier, to hasten the acquisition of wealth or to save time, health or worry. The fixation of nitrogen is a question of the not far distant future. Unless we can class it among certainties to come, the great Caucasian race will cease to be foremost in the world and will be squeezed out of existence by races to whom wheaten bread is not the staff of life.

This solemn warning aroused the scientific world to the importance of nitrogen fixation, but after nearly a quarter of a century it is only a few in our nation who appreciate the vital importance of this problem.

Our National and Industrial Pre-eminence Dependent on Fixed Nitrogen

This discussion of the question of fertilizers and explosives has hinged largely on the question of supply of fixed nitrogen. From the military standpoint, our situation is much better than in 1917 and it would seem that our coke ovens with their increased production and the private plants for nitrogen fixation, with the government plants standing as a reserve, are sufficient to provide explosives for national defense.

The maintenance of our soil fertility stands out as a far larger problem. The United States will have to struggle to maintain its industrial pre-eminence and its high standards of living in the face of decreasing natural resources. Our soil fertility has been our greatest asset. As New England farms became unproductive their occupants moved to the Ohio and Mississippi valleys, where the soil produced in as rich a measure as the world has ever known. Even these marvelous soils are deteriorating.

The elements taken from the soil must be put back into it. The most important single constituent is nitrogen. Agriculturists have shown that it is possible to replace this by a system of crop rotation, but it involves an absolute lack of return from the soil during every fourth year. The increase in the value of farm land has greatly increased the expense of this process through the increase in fixed charges and has correspondingly increased the opportunity of the chemical engineer to produce fixed nitrogen at a price which can compete with this method of fertilization through biological processes.

The principles of nitrogen fixation are clearly outlined but the developments are still in their infancy. The process of the synthesis of ammonia through direct

combination of nitrogen and hydrogen presents possibilities and difficulties which challenge the best efforts of our chemical engineers, for this process has been called the most difficult chemical engineering operation which has ever been undertaken. The fixation of nitrogen can be accomplished as a military measure. Can it be accomplished so economically that it can produce the nitrogen needed by this country to maintain its soil fertility? That remains for the future.

In our study of national preparedness, we may list the raw materials for explosives as adequate, but the personnel which is to guide the future development is largely dependent on the fate of the dye industry and its related industries which deal with synthetic organic chemicals. The importance of a far greater supply of nitrogenous fertilizer is hardly yet recognized. The agriculturist through crop rotation and biological processes can meet the need in part. Can the chemical engineer develop the processes of nitrogen fixation so that the soil will remain productive and our children and our grandchildren live as comfortably as we do?

History shows that the fallen nations of the world either perished from exhaustion of the soil or were conquered by a hardier race after they had lost much of their original vigor through too much prosperity or indulgence. In either case they had failed in national preparedness. It was pardonable in the days of the dawn of civilization. It will be unpardonable if we, with our knowledge of the mistakes of the past and with the powerful weapons of modern science in our hands, make the same mistakes.

Fusibility of Open-Hearth Slag Containing Titanium Dioxide

By George F. Comstock
Titanium Alloy Manufacturing Co., Niagara Falls, N. Y.

THE comparative fusibility of basic open-hearth slags from soft steel heats and of similar slags with small additions of titanium dioxide has recently been investigated in the physical laboratory of the Titanium Alloy Manufacturing Co., with interesting results. Two slags were used in this work, one from the Wickwire-Spencer Steel Corporation in Tonawanda, N. Y., and the other from the National Enameling & Stamping Co. in Granite City, Ill. The former had a very much lower melting point than the latter, so that it could be melted in a coke fire, while with the latter this method was impracticable. The experiments with the low-melting Wickwire slag will be described first.

This was melted in small crucibles in a coke fire, two No. 12 Dixon graphite crucibles and one old crucible of about the same size, formerly used for bronze, being consumed in these trials. The corrosive action of the slag and the high furnace temperatures required for the melts caused the crucibles to wear out very fast. Plain crushed slag was first melted and taken out in the furnace to cool in the air, while various methods of determining the freezing point were tried. Owing to the viscous consistency and poor thermal conductivity of the slag, this determination was a much less simple matter than a similar determination is with metals. The slag passes very gradually from the liquid to the solid state through all stages of plasticity, and during cooling no two layers in the crucible are at the same temperature. Consequently a thermocouple inserted in the cooling slag gives a series of gradually decreasing readings, with any stationary period such as denotes the freezing point of a metal. It was planned therefore to note the progress of solidification by visual observation while stirring the slag, using a thermocouple and an optical pyrometer to give temperature measurements when the slag seemed to be just solid.

In the first trial, a nichrome tube closed at one end was inserted into the slag in the furnace and heated until all was at a uniform temperature, and the pot with the tube in it was withdrawn and permitted to cool. A quartz tube containing a platinum thermocouple was inserted in the nichrome tube, and the slag was stirred till it solidified, while readings were also taken on the liquid slag with the optical pyrometer. By this method the freezing point was determined as 1,175 deg. C. by the thermocouple and 1,115 deg. C. by the optical pyrometer. But on removing the thermocouple the quartz tube was found to be contaminated by slag, as the end of the nichrome tube had been burned off. A new iron tube was tried, but did not last any better, so finally a graphite tube had to be used. In another trial both pyrometers agreed fairly well on a freezing point at 1,110 deg. C.

A next trial was made with powdered slag to which 0.33 per cent TiO_2 was added, which was intended to represent the proportion of titanium which the slag would acquire by the total oxidation of the usual 3 lb. per ton addition of ferro carbon-titanium in soft steel. This addition would amount to about 0.5 lb. of titanium, or roughly 1 lb. of oxide per ton of steel, while the slag made was estimated at 15 per cent, or 300 lb. per ton, of steel. The mixture of 1 part TiO_2 to 300 parts slag was melted four times, and temperature measurements were made on it each time it cooled. The thermocouple in the carbon tube did not prove a very satisfactory arrangement, however, as the slag froze around it and it interfered with stirring because it could not be moved freely with the pyrometer wires and quartz tube in it. Also the optical readings on the slag itself were unsatisfactory, because the surface of the melt was always cold, and even when the skin was broken the hot liquid became covered at once with a cooler film before a reading could be taken. Consequently the best plan seemed to be to use the graphite tube as a stirrer, without any thermocouple in it, and to get the temperature measurements by sighting down into its hot end with the optical pyrometer. This method probably gave slightly low readings on account of the loss of heat from the hot end to the colder top of the tube, but it was convenient in operation and seemed to give concordant and regular results. All further trials were made in this way.

Such observations on the 0.33 per cent TiO_2 mixture described above showed a freezing point of about 1,085 deg. C. The crucible was thoroughly cleaned out after this trial, and another melt of the plain slag without titanium was made by the same method. Three tests in this way gave an average reading of 1,085 deg. C., showing that the addition of 0.33 per cent TiO_2 had no appreciable effect. In both these trials considerable white cast iron was reduced from the slag by the carbon of the crucible and tube during the repeated meltings, and the crucible was entirely used up at the end of this trial. No way of avoiding the reduction of iron from the slag could be thought of, with the melting facilities available.

Two separate trials, each consisting of several remeltings and in different crucibles, were made of this slag mixed with 1.33 per cent TiO_2, the proportion assumed to

be acquired from the recommended addition to rail steel. These trials resulted in freezing points of 1,060 and 1,055 deg. C., respectively, being found. Another trial was made with twice as much TiO_2, giving a result of 1,025 deg. C. Thus it seems that larger quantities of TiO_2 do indeed lower the melting point of basic open-hearth slag, and the slags from these latter trials were noticeably thinner when hot and more glassy when cold.

A final trial of the plain slag to check the first result of 1,085 deg. C. was made, and a lower result—namely, about 1,065 deg. C.—was obtained. It was noticed on the last few trials that after the first melting the slag generally showed a comparatively high solidification temperature, while on subsequent meltings it remained liquid when colder. It is believed that the slag as received was in a chemically unstable state, with certain compounds incompletely formed, and that a considerable period of fusion and quite a high temperature are required to complete these reactions. This condition would involve various uncertainties in the action of titanium dioxide on the slag in open-hearth practice, for the results would depend on the exact condition of the slag when this oxide entered it and the time available for combination to take place before freezing. In view of these uncertainties arising from the unstable and probably irregular composition of the slag, its viscosity and low thermal conductivity, the results described above are probably as accurate as it is worth while or possible to get them. They may be summarized in Table I.

TABLE I—SOLIDIFICATION POINTS OF SLAG FROM WICKWIRE-SPENCER CO.

	Deg. C.
Plain slag	1,065 to 1,085
Slag with 0.33 per cent TiO_2	1,085
Slag with 1.33 per cent TiO_2	1,055 to 1,060
Slag with 2.67 per cent TiO_2	1,025

Results on this slag indicate that titanium dioxide increases the fusibility of basic open-hearth slag, but not unless it is present in amounts greater than that available from the usual alloy addition to soft steel. If it may be assumed, however, that all the titanium is oxidized in the steel, and this oxide combines first with the slag particles included in (not resting on) the liquid steel, almost any percentage of TiO_2 might be present in these particles from a very small total titanium addition to the bath. Thus the fact that 2 or 3 per cent of TiO_2 made quite a noticeable improvement in the fusibility of this slag may be of practical interest and importance, even though the entire slag from a titanium-treated open-hearth heat may never reach this comparatively high TiO_2 content.

The other slag sample available, from Granite City, could not be melted by the coke fire, so that a different method had to be used with it. The only other method which appeared practicable with the heating equipment available involved making briquets or cones of the crushed slag, standing them up on a magnesite brick in a small reverberatory furnace which could be made very hot by two high-pressure oil burners, and noting with the optical pyrometer the different temperatures at which they sagged or bent over when softened by the heat.

A trial of this method having been decided upon, a mold of steel was first made for the briquets, which were to be in the form of a rectangular wedge, with sides 2 in. high and ends in the form of equilateral triangles of ½ in. base. The granular material for the briquets was moistened with a dilute solution of dextrine to act as a binder, and packed in the mold, which was previously lined with paper to prevent sticking. Twenty to fifty thousand pounds pressure was applied to the mold in forming the briquets, but they were not very firm until after drying. This operation was performed over night at about 100 deg. C. and the next morning they were hard enough to stand handling readily.

The first trial of this method showed that it was necessary to grind the slag to at least 100 mesh in order that the briquets should be sufficiently resistant to cracking or spalling in handling and heating and that the dried briquets must be dressed to an exact size and shape to insure proper comparative results in the furnace. These precautions were taken therefore in the experiment with this slag, and two briquets were made without any addition and called No. 1; two others, with 0.33 per cent TiO_2, were called No. 2; two others, with 1.33 per cent, No. 3; and finally two with 4 per cent TiO_2, called No. 4. These were all stood up on a level magnesite brick in the oil-fired furnace, with bricks placed behind to protect them from the direct blast of flame. The temperatures were taken with an optical pyrometer.

The No. 4 briquets began to bend at 1,285 deg. C., and one failed at 1,305, the other at 1,325 deg. C. The No. 3 began to bend at 1,333 deg. C., failing at 1,348 and 1,358 deg. C., respectively. The No. 2 began to bend at 1,360 deg. C. and bent over completely at 1,373 and 1,377 deg. C., respectively. The No. 1 briquets began bending at 1,385 deg. C., and one failed at 1,418 deg. C., while the other remained upright, but was considerably melted down at 1,458 deg. C., when the furnace was shut down. These results, tabulated in Table II, are very regular and satisfactory, checking those obtained on the Wickwire slag except that all the temperatures are much higher, and even the 0.33 per cent addition of TiO_2 was found to increase the fusibility quite decidedly.

TABLE II—TESTS OF BRIQUETTED SLAG FROM NATIONAL ENAMELING & STAMPING CO.

	Beginning of Bend, Deg. C.	Failure, Deg. C.
Plain slag	1,385	1,418 to 1,460
Plain slag with 0.33 per cent TiO_2	1,360	1,373 to 1,377
Plain slag with 1.33 per cent TiO_2	1,333	1,348 to 1,358
Plain slag with 4 per cent TiO_2	1,285	1,305 to 1,325

It is interesting to note that both under the reducing conditions of the graphite crucible and in the oxidizing atmosphere of the oil furnace the TiO_2 had a distinctly fluxing action on the slags, so that the action could scarcely be any different under the intermediate conditions existing in the region between metal and slag in an open-hearth steel ladle. The amount of TiO_2 actually acquired by slags in practice from titanium treatment is of course more or less questionable and variable, but in one series of fourteen soft steel heats of which half were treated, the average TiO_2 content of the final slags from the seven treated heats showed an increase of 0.33 per cent over the average for the seven untreated heats, which is exactly the theoretical increase assumed. However, as explained in a paragraph above, it is really the slag included in the metal which it is desired to make more fusible for the sake of cleanness, and the increase in TiO_2 content in these included particles would undoubtedly be higher than in the whole mass of slag, so that the effect of more than 0.33 per cent of TiO_2 is also of practical importance.

Purification of Cotton Linters for the Manufacture of Guncotton and Various Pyroxylin Products

Production of Cotton Linters—Equipment for the Purification of Linters: Digesters, Wash Tanks, Bleach Tanks, Stuff Chests, Surge Tanks, Caustic Tanks, Bleach House, Dry House—The Purification Process—Purification for Pyroxylin Products

By W. STARK

THIS article is being written with the thought that it will perhaps be interesting and informing to those who were not brought into direct contact with the huge munition plants erected in this country beginning with the war in 1914 and reaching their zenith of expansion in the latter part of 1918. The present article has to do only with the conversion of the crude fiber into pure cellulose, from which it passes through the various stages to guncotton, and thence into finished smokeless power, and is a description of the process as applied in the Du Pont plant at Hopewell, Va., and the U. S. Government explosive plants located at Nitro, W. Va., and Nashville, Tenn.

It will be recalled that the United States at the time of the armistice was producing approximately 3,000,000 lb. of smokeless powder a day, and since the conversion factor from cellulose to smokeless powder is approximately 1.5, this meant that 2,000,000 lb. of cellulose had to be produced to be converted into this quantity of powder.

Raw cotton is probably the purest form of cellulose as it occurs in nature, but owing to the high price of this product and its value for the manufacture of cloth, cotton linters and hull fiber were used in its stead. Aside from this fact, ordinary cotton lint has such a long fiber that it packs in going through the various mechanical and chemical processes, and this fact alone precludes its use as a raw material for this purpose.

Production of Cotton Linters

Cotton linters is the fuzzy fiber adhering to the cotton seed after it has been ginned. It is removed by a process known as delinting. The fiber of linters is usually about $\frac{1}{16}$ in. long and leaves the outer shell of the cotton seed exposed. The outer shell of the seed, however, contains considerable cellulose, and the necessities of the situation were such during the war, owing to the large demands for any form of cellulose, that mills were erected to shave the outer shell of the seed and produce the material known as hull fiber.

The recovery of cellulose from cotton linters on a 10 per cent moisture basis, after going through the purification process, is about 82 per cent, the remaining 18 per cent being removed in the form of oil and impurities; the recovery of cellulose from hull fiber is about 45 to 50 per cent. In actual practice, therefore, these raw materials were mixed in the proportion of 60 per cent linters and 40 per cent hull fiber as they entered the digester.

When it is remembered that the annual production of cotton linters in this country is 1,250,000 bales of 500 lb. each per year, and the production of hull fiber during 1917 was only 500,000 bales of the same weight, it will be seen that, with the large quantities of powder being manufactured at the time of the armistice, it would soon have become necessary to use wood to a large extent for the manufacture of cellulose for this purpose. It is to be assumed that Austria and Germany were almost entirely dependent on wood for their source of raw material in this respect.

Equipment for the Purification of Linters

The purification building in its essential details consists of eight welded steel digesters, 27 ft. long and 9 ft. in diameter and $\frac{1}{8}$ in. thick in the shell. These digesters are designed to stand a pressure of 150 lb. per sq.in., and at the top there is an opening 30 in. in diameter, which is for the purpose of charging. This opening is closed by the digester cover during the digesting and blowing period. At the bottom center of the digester is a 10-in. valve connecting the digester proper with a 10-in. line which extends to the cyclone tank at the top of the building and enters the tank tangentially. These digesters are set on a steel foundation and are covered with asbestos to conserve the heat during the cooking period. It is into this cyclone tank that the whole charge of cotton and caustic solution is blown after digestion has taken place. At the top of the cyclone tank and extending through the top of the building is a 24-in. vent to release the steam that is the motive force used to raise the charge to the tank from the digester, a distance of approximately 125 ft. The charge flows from the tank by gravity and force, through a 30-in. diameter swinging spiral pipe to the wash tanks. Each cyclone tank serves two digesters, as the blowing of the charge takes only about 5 minutes. The spiral pipe can be swung so as to discharge into either of two wash tanks and after each blow this pipe drips into a drip tank which takes care of any caustic which may flow through it for some time after the main charge. This drip tank has a false perforated bottom and empties into the main spent caustic line.

Wash Tanks

The wash tanks, one for each digester, are made of steel and are 10 ft. in diameter by 16 ft. deep and have a false bottom and a three-arm agitator operated by a gear, which in turn is connected to the drive shaft by a clutch. The whole charge of cotton and caustic flows into the wash tank and the spent caustic passes through a pipe at the bottom of the tank into the main spent caustic line and from there to the drain, or, if the plant has a caustic recovery unit, to the spent caustic storage tanks. There is naturally a

valve in the line connecting the wash tank with the main caustic line. The wash tanks are supplied with water jets, both for cold and hot water, which are located at the top of the tank and are so arranged that the spray covers the entire surface of the charge.

Bleach Tanks

The bleach tanks are the same size as the wash tanks and are located directly below them. They are made of cypress and other suitable wood, have individually driven three-arm agitators and are connected with the wash tanks by a 16-in. line and a 16-in. quick opening valve through which the washed cotton drops by gravity. These tanks have a perforated false bottom and a pipe connection to the main drainage line. It is desirable to have a compressed air connection entering the bottom of the bleach tanks below the false bottom so that agitation will be facilitated during the bleaching operation.

Stuff Chests and Surge Tanks

Stuff chests made of wood and the same size as the bleach tanks are located directly below them and on the main floor of the purification building. They are connected with the bleach tanks by a 16-in. line and a corresponding quick opening valve. They have a compressed air connection at the bottom, but no agitators, and at the bottom there is a 6-in. line with a centrifugal pump which lifts the bleached charge to a lead-lined trough, through which the charge flows to the dry house. This trough is set at such a pitch that the charge flows freely through it to the surge tank, which is located on the far side of the dry house from the purification building. As the flow passes through this trough a sufficient amount is taken out at the washer of each drier by automatically operated gates. The charge in the surge tank is agitated constantly and a centrifugal pump circulates the charge from the surge tank to the main trough at a point between the purification house and the dry house. A float in the surge tank operates lights in the purification house, which indicate to the operators when the surge tank is full.

Dissolving Caustic

The strong caustic storage and dissolving tanks, two in number for each building, are on the top floor of each building, are made of steel and have false bottoms, and have a circulating system for the more rapid dissolving of the drum caustic and to secure a homogeneous mixture of the caustic solution. Either solid drum caustic is used or caustic solution made from soda and lime. This is pumped from the caustic plant. At Hopewell both were used, as the caustic plant was not sufficiently large to produce the 200,000 lb. of caustic used daily. After the caustic has been thoroughly dissolved, a sample is taken to be titrated, using a standard acid solution and methyl orange as indicator. From this analysis it is determined how many pounds of strong caustic is necessary to make up the caustic charge to be pumped into the digester.

Preparation of Weak Caustic Solution

Just below each strong caustic tank there is a weigh tank with a capacity of 40,000 lb. of solution. This weigh tank is of course connected with the caustic tank above, and has connections with both the hot and cold water supply. After the caustic charge has been prepared in the weigh tank, where it is thoroughly agitated, it is referred to as "weak caustic" (usually 2 per cent) and is dropped to the weak caustic storage tanks, six in number, located on the main floor of the purification building. These tanks are the same size as the caustic weigh tanks and have steam coils in them so the caustic can be heated to the proper temperature before entering the digester. From these storage tanks the caustic is pumped to the digesters when ready for use.

Bleaching Solution

The bleaching solution is prepared in a separate house, which consists of the requisite number of leaching tanks with agitators and storage tanks. Chlorinated lime is used containing about 33 per cent chlorine and a solution is made containing about 2 per cent chlorine. After the solution has become perfectly clear, it is siphoned off to the storage tanks in the bleach house and is then pumped to the bleach measuring tanks in the purification house. There are two of these tanks to each purification house, set on the floor above the bleach tanks so that the solution can flow by gravity to them. They are equipped with a suitable measuring device so that the requisite amount of solution can be readily drawn into the bleach tanks for each charge.

Drying Equipment

Each purification house has its corresponding dry house. These consist of six Sargent continuous apron driers. The cotton flows from the trough mentioned above through a chute to the washer of the drier, where the rake moves it constantly to the rolls. It is the movement of this rake which automatically operates the gates of the trough through which the cotton flows to the chute. The rolls press the cotton into flakes about the size of one's hand and deposit them on an apron, which in turn drops them into a picker, which breaks the flakes into a fluffy mass. This mass then passes on to the wire apron of the drier proper and slowly moves forward toward the exit, coming out in the form of a solid sheet. The cotton as it enters the drier contains about 80 per cent moisture and emerges at the end of the drier containing about 1 per cent moisture, from which point it is put into metal or fiber cans, weighed and sent over the telpherage line to the nitrating houses. The drier is heated by steam pipes and the temperature is kept at about 125 deg. C.

The Purification Process

The cotton is brought in bales from the crude fiber storage warehouses on an industrial railway and is carried to the charging floor of the purification houses. Here it is weighed, the tare deducted and each bale broken up and dropped into the digester. The tops of the digesters are flush with this floor. The amount of each charge is 5,000 lb. After the cotton is placed the caustic from the weak caustic storage tanks is pumped in and the covers are adjusted. Steam is then turned into the digester and the pressure raised to 65 lb. per sq.in. and the cooking proceeds for about 5 hours, the hot caustic dissolving the oils, fats resins and other impurities contained in the cotton. After digestion is completed, steam pressure is raised to 90 lb. per sq.in., the 10-in. valve at the bottom o

the digester is opened and the whole charge blown to the cyclone tank.

In the wash tanks about three successive washings and drainings are sufficient to dispose of the spent caustic contained in the cotton and the charge is then dropped to the bleach tanks, where sufficient bleach solution is added to turn the cellulose perfectly white. Bleaching proceeds for about 3 hours at a temperature of 30 deg. C., and after about 2 hours a sufficient amount of sulphuric acid is added to the charge to drive off any remaining chlorine. The charge is then dropped to the stuff chests ready to be pumped to the dry house when needed.

It will be understood that from the time each charge of cotton enters the wash tanks until it enters the driers it is suspended in about 5,000 gal. of water. Using a mixture of 60 per cent linters and 40 per cent hull fiber, the original charge of 5,000 lb. gives a recovery of about 3,500 lb. of purified cotton, estimated on the basis of 10 per cent moisture.

At the end of one of the driers in each dry house a fan is located connected with a 10-in. galvanized iron pipe line which leads to a bale house. When the production of cotton is greater in the purification area than the nitrating houses can utilize, the excess is baled and stored. It is then used when the nitrating houses are consuming more than the purification area can produce. This discrepancy in balance is caused by bad charges in the purification houses and an undue number of explosions in the nitrating houses.

The purification of cotton for the manufacture of celluloid, fabrikoid, moving picture films and other pyroxylin products follows this same general principle except that in such cases a superior grade of linters is used, a stronger caustic solution is required, the cooking period is extended and a longer period of bleaching is necessary. Also in the manufacture of these pyroxylin products, extreme care must be taken that no dust or other impurities enter the charge at any stage of the process.

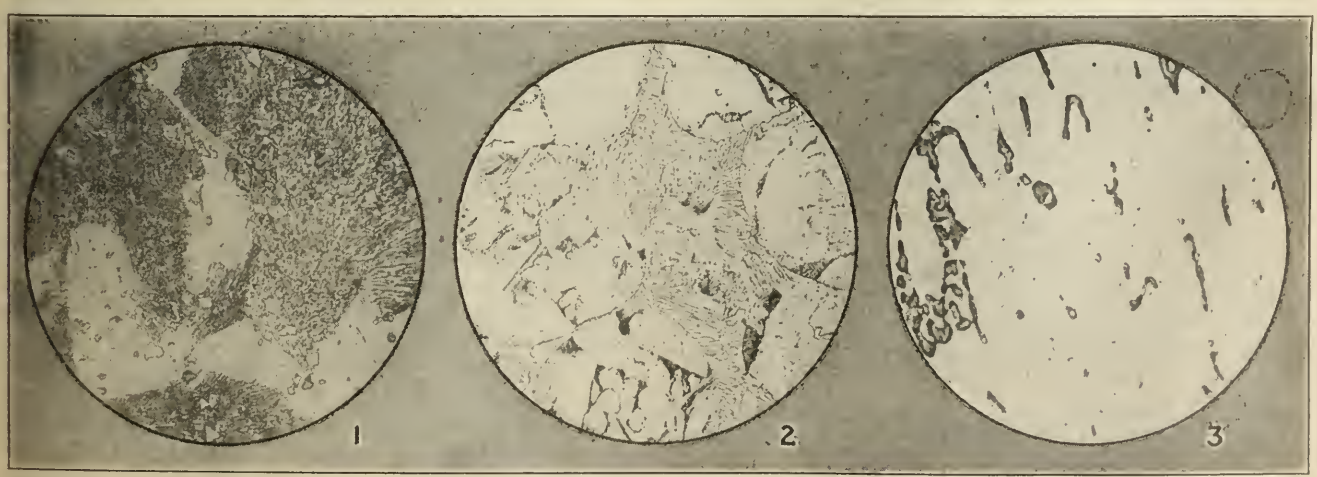
Steels With Zirconium, Cerium or Boron

AN INVESTIGATION to determine the utility of certain rare-metal alloy steels when used for body armor is shortly to be published by the Bureau of Standards. About 193 heats of steel containing in various combinations the following principal variable elements: carbon, silicon, nickel, aluminum, titanium, zirconium, cerium, boron, copper, cobalt, uranium, molybdenum, chromium and tungsten, have been studied.

Zirconium, like titanium and aluminum, acts primarily as a scavanger, and when it is not removed as part of the slag remains in the steel, as shown in Fig. 1, in the form of square bright yellow inclusions not directly visible at magnifications much lower than 500. The Bureau of Standards does not consider that these inclusions can be very beneficial and if they are segregated and rolled out into thin plate-like streaks they may be detrimental, especially in armor plate.

Of the other elements that are regarded as special alloying additions, chromium, tungsten, vanadium and molybdenum go into solution and produce a martensitic pattern in the air-cooled specimens. Cerium and uranium act in a similar manner, but also show characteristic inclusions. Copper goes into solution, but a larger amount is required to produce a martensitic pattern in the air-cooled samples than for the others.

Figs. 2 and 3 show the structure of boron steel (Fig. 2, carbon 0.16, boron 0.49, nickel 2.82; Fig. 3, carbon 0.16, boron 0.39 per cent). When the attempt was made to roll this steel under the same conditions used with satisfactory results for steels of similar composition but containing no boron, the metal crumbled and cracked badly in the rolls. Indeed, some ingots were so brittle that they broke under their own weight when carried from the furnace to the rolls. By heating the ingots for a sufficiently long time until considerable coalescence of the eutectic occurred and by reducing the temperature of the ingot somewhat—that is, below the eutectic temperature—no unusual difficulties on working the metal were encountered. As shown in Fig. 3, hot-working breaks up the eutectic and spherical hard particles, similar to iron carbide globules, are formed.



FIGS. 1 TO 3

Fig. 1—Microstructure of steel to which additions of zirconium have been made. × 425. The small light-colored inclusions, square or triangular in outline, are characteristic of steel to which zirconium has been added. They are of a striking lemon-yellow color. Etching reagent, 2 per cent alcoholic solution of nitric acid.

Fig. 2—Section of an ingot of boron steel which broke in the rolls and could not be worked. The addition of the boron causes the formation of the eutectic shown. Etching reagent, 2 per cent alcoholic solution of nitric acid. × 425.

Fig. 3—Longitudinal section of a rolled plate of boron steel, showing the coalescence of the eutectic which has occurred. Etching reagent, hot alkaline solution of sodium picrate, coloring the carbide a dark brown and sometimes nearly black. × 425.

Colloidal State in Metals and Alloys III—White Metal and Brass

Solid Solutions and Eutectics, Just Before Solidification, Are Adsorption Compounds—Copper in Alpha Brass Aggregates So Rapidly That Zinc Is Only Partly Adsorbed; Hence Cored Structure—Laminated Eutectic Caused by Skeletal Solidification of Predominating Partner*

BY JEROME ALEXANDER
President, Uniform Adhesive Co., Brooklyn, N. Y.

THE presence in a metal of a second metallic or non-metallic element, whether as an intentional addition or as an accidental impurity, opens a wide range of possibilities, which may be roughly outlined as follows:

1. The second element may form a definite compound with the metal, or it may not.

2. If formed, the chemical compound may be stable at all temperatures or only within a certain temperature range; or there may exist a reversible equilibrium, with a lag on either side of the equilibrium point.

3. The second element or its compound with the metal may be soluble in or miscible with the metal in all proportions; or, as usually the case, there may exist zones of thermal or percentage solubility, dispersion or peptization; or even practical non-miscibility at all temperatures, in which case there usually is a certain degree of segregation.

4. Dissolved or dispersed elements or compounds may materially alter the melting point, viscosity (internal friction), surface tension, vapor pressure, freezing point, conductivity, allotropic equilibrium, and crystallization tendencies of the metal.

The presence of still other additional elements complicates the situation correspondingly; and when to this welter of variable factors we add the further complications of the effects of mechanical treatment and the thermal history of the section of metal under consideration (which involves such factors as speed of chilling, size and shape of the original mass, hot and cold working, tempering), we can well imagine why it is impossible to frame one general law covering the protean behavior of impure metals and alloys. Each case must be individually considered.

The attempt will be made, therefore, to consider some well-known metallurgical phenomena[1] in the light of the colloid-chemical principles above referred to.

TIN-LEAD ALLOYS

Considering first the binary system between tin (melting point, 232 deg. C.) and lead (melting point, 327 deg.) (Fig. 1), it is found that all the alloys melt at a lower temperature than the melting point of lead, which is an instance of the general rule that the freezing point of a solvent is lowered by the presence of a solute. Of all the alloys, that consisting of 63 per cent tin and 37 per cent lead has the lowest melting point, a fact indicated by its Greek-derived name "eutectic." If the metals are mixed in other than eutectic proportion, the excess metal tends to crystallize out alone on cooling, leaving in still fluid condition the maximum possible amount of eutectic, which solidifies later. That the eutectic does not consist of a chemical compound is brought out by the microscope, which reveals its heterogeneity; it is usually laminated and can be brought into relatively coarse dispersion by slow cooling.

But some forces do control the formation of the eutectic, and the mechanism seems to be the following: As the fused alloy approaches solidification, the lead, having the higher melting point, first begins to form molecular groups, crystallogens or tiny crystals. This aggregation of the lead molecules is opposed by the more fluid tin, which accounts for the lowering of the freezing point of the mixture. Diminishing thermal agitation permits the tin to form groups and a stage is reached where both metals exist largely in colloidal state.[2] In this zone a colloidal adsorption compound is formed, the ratio 63 tin to 37 lead being consequent upon their specific forces; and any excess of tin or of lead is free to crystallize independently. In the eutectic, although tin tends to crystallize rapidly, the adsorbed lead interferes with its crystallization to such an extent that, if quickly cooled, its structure is extremely fine.

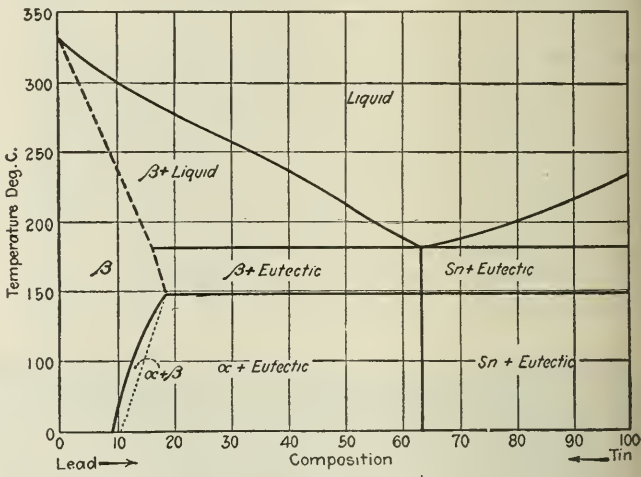


FIG. 1. EQUILIBRIUM DIAGRAM FOR LEAD-TIN ALLOYS. AFTER ROSENHAIN

The present series of papers was written mainly in the fall of 1919. Reduced to about half their original form, they were read before the Columbus meeting of the American Insitute of Mining and Metallurgical Engineers, October, 1920, and will so appear in vol. 64 of its *Proceedings*. They are now given in full, together with some recent additions which are indicated by enclosure within square brackets [].

*Part I, on Molten Metal, appeared in CHEMICAL & METALLURGICAL ENGINEERING, Jan. 11, 1922, p. 54; Part II, on Crystallization, in the issue of Jan. 18, 1922, p. 119.

[1] I have made free use of, and frequently quoted from W. Rosenhain's excellent book, "Introduction to Physical Metallurgy," D. Van Nostrand Co., 1914.

[2] All metals in solidifying pass through an isocollodial zone, the narrowness of which is indicated by the sharp peak or cusp in the inverse-rate curve, see Rosenhain, pp. 85-87, and Part I of the present series of articles, CHEM. & MET. ENG., vol. 26, No. 2, p. 54, Jan. 11, 1922.

As with all colloids, this represents a metastable condition, and if the temperature is kept within limits which permit molecular orientation without disruptive thermal agitation, the eutectic undergoes a gradual synæresis analogous to coagulation or demulsification—a further separation into its constituent phases.[3] The laminated structure, common in eutectics, already represents the coagulation of the pre-existing colloidal dispersion, as will be especially pointed out later in the discussion of pearlite in steel.

Eutectic Structure

Speaking of the tin-lead eutectic, Rosenhain says on p. 133 of his "Introduction to Physical Metallurgy" that "this laminated character, though often beautifully marked, is not to be regarded as an essential feature of these substances. If a specimen of a well-laminated eutectic is heated for a long time at a temperature a few degrees below its melting point, the structure gradually changes, various laminæ coalescing to form lumps or globules, and the result is a much coarser granular structure. Such a granular structure may also be obtained if the molten eutectic is very slowly cooled.

"The eutectic alloy is the result, so far as its structure is concerned, of the simultaneous crystallization or freezing of the two component metals. As a rule one of these metals acts as the 'predominant partner,' and its own crystalline form or habit determines the way in which the whole structure is arranged. It has been shown that eutectic alloys, like pure metals, consist of an aggregate of juxtaposed crystals. These crystals are, however, merely skeletons formed of one of the metals—'the predominant partner'—with the interstices filled in by the other metal. In the case of the lead-tin alloys,

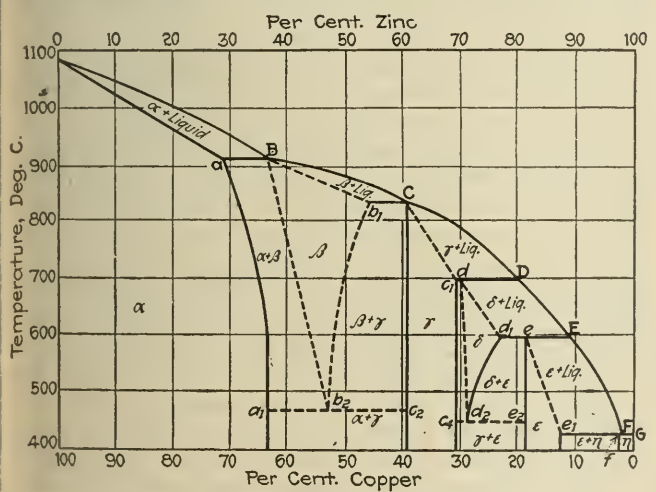

FIG. 2. EQUILIBRIUM DIAGRAM FOR COPPER-ZINC ALLOYS, AFTER GULLIVER

the tin is the predominant metal, and each of the crystals of the eutectic is in reality a radiating structure, known as a 'spherulite,' of tin carrying the lead in its interstices." This is clearly a picture of tin crystallized in the presence of adsorbed lead. Although tin has a lower melting point than lead, its superior crystallization power and speed make it predominant.

Rosenhain also points out[4] that lead-tin alloys containing up to about 16 per cent of tin form a series of solid solutions, which approach their true equilibrium condition very slowly; "it was found that heating at a temperature of 175 deg. for a period of 6 weeks was required in order to bring the alloys approximately into their final state." This is indicative of the slowness with which the tin in these alloys is peptized or dispersed by the lead. Another observation is that the lead-tin alloys "exhibit an evolution of heat on cooling and a corresponding absorption of heat on heating at a temperature which lies, for alloys containing from 16 to 23 per cent of tin, at 149 deg." Rosenhain's explanation is that this is due to the diminution at that temperature of the capacity of lead to dissolve tin. In any event there is some form of non-stochiometric molecular aggregation, accompanied by an evolution of heat, quite analogous to what happens when silver hydrosols coagulate. Thus J. A. Prange found[6] that upon precipitation by ammonium citrate 1 g. of colloidal silver developed from 250.98 to 126.73 calories, depending upon the concentration of the solution; and the further aggregation of the precipitate by H_2SO_4 set free 60 calories more. But here restraining water films were present, and the final product was not yet solid metal.

[The metastability of metals and matter generally has been studied by Prof. Ernst Cohen (Utrecht). At a lecture delivered recently in London[8] he exhibited specimens of explosive antimony, which when scratched, were converted into ordinary antimony with a heat evolution of 20 calories per gram of metal.[7]]

Another point of interest in the lead-tin alloys is found in solder used by plumbers for wiping joints. At about 210 deg., this alloy begins to extrude crystals of lead into the still fluid eutectic cement, rendering it pasty and easy to mold into the desired shape. Here the eutectic acts as a viscous colloid or glue thickened by the addition of clay or other fine insoluble filler.

Bearing Metal and Brass

The introduction of the highly crystalline antimony (melting point 630 deg. C.) into the lead-tin alloys results in the early formation of crystals of antimony or of the hard brittle compound SnSb, with the result that the ternary alloy is much harder. Type-metal, which varies in composition according to price and service conditions, is usually chilled quickly, which is conducive to hardness and fine structure. White bearing metals, on the other hand, are usually cast in larger masses and chill more slowly; and their composition is chosen to yield, under these circumstances, hard wear-resisting crystals of SnSb imbedded in a colloidal plastic eutectic, which can adapt itself to the bearing's irregularities of shape and pressure.

A consideration of the zinc-copper alloys shows how vitally treatment and composition affect the nature and degree of dispersion of their phases. Brasses containing less than 30 per cent of zinc, whether quickly or slowly chilled, always consists of a solid solution of zinc in copper, known as the pure α body;[9] but it does not follow from this that the alloys are necessarily homogeneous in all circumstances. If we recall the process of freezing, as already described for a solid solution, we see that in the case of an alloy containing, say, 20 per cent of zinc, the solid which first separates when the alloy *begins* to freeze will have approximately the composition 13 per cent zinc, 87 per cent copper. If the cooling at this stage is not slow enough to permit

[3] With tin-lead alloys, this occurs at room temperature.

the attainment of complete equilibrium, the central portion of each crystal—i.e., the portion first formed—will remain to the end considerably richer in copper than the outer or later-formed crystals. Each crystal of metal of such composition will, in the circumstances, consist of a core which is richer in copper, and an outer portion which is poorer in copper, than the average composition of the alloy. A quickly cooled alloy in the cast condition thus shows an apparent duplex structure (Fig. 3), although consisting only of one phase,[9] for although the layers of solid solution of varying concentration which form these crystals are all of the same α phase, their different concentration renders them susceptible to the attack of etching reagents to different degrees; by most reagents the regions richest in copper are less attacked than those which contain a larger proportion of zinc. Since those portions of the crystals first formed consist of the dendritic branches occurring in the early stages of freezing, the etched pattern of an alloy reveals this dendritic structure, and in some circumstances this may be almost as clearly defined as if the outer regions consisted of a different phase.

"When, however, such an alloy is slowly cooled, or, after rapid initial cooling, is subsequently heated so as to allow the attainment of equilibrium by the slow process of diffusion, the metal becomes entirely homogeneous,[9] the dendritic cores disappear, and we have again the familiar aggregate of homogeneous crystals such as are seen in all pure metals. It should be noted that the mechanical work and subsequent annealing which occur in the working of brass as usually carried out are also sufficient to render the metal homogeneous in this sense,[10] with the result that wrought brasses containing less than 30 per cent of zinc do not as a rule show any trace of dendritic structure; their structure is in fact very similar to that of pure copper when treated in the same way—i.e., it consists of an aggregate of twinned[11] crystals whose size depends upon the manner of heating and working."

FIG. 3. SKELETON CORES IN LARGE α GRAINS OF 93:7 COPPER: TIN ALLOY
Etched with solution of Br in HCl. After Heycock and Neville. × 18.

These facts seem to me to indicate that α brass is really an adsorption compound between copper and zinc, in which the large percentage of copper with the high melting point of 1,083 deg. aggregates so rapidly that even in so-called quickly cooled specimens, the zinc with a melting point of 419 deg. C. is for the most part still so finely dispersed as to be only partly adsorbed by the copper; hence we expect to find a dendritic structure which shows a copper crystallization as modified by adsorbed zinc, the amount of which increases from the center outward as the copper aggregates and the mother liquor becomes richer in zinc. It is probable that small pieces of α brass drastically quenched from fusion in liquid air would appear homogeneous in the microscope. As Rosenhain points out, the percentage of each metal and its state of aggregation are varying momentarily during cooling, and because of the wide disparity between the melting points of the two metals, homogeneity is favored in this case either by extremely rapid quenching from fusion or else by slow cooling or annealing, which favor more complete dispersion and adsorption of the "segregated" zinc.

With brasses containing 30-37 per cent of zinc, there appears a new hard, brittle, metastable phase, β brass. Such brasses if quickly cooled are relatively hard and brittle, but if cooled slowly the β phase disappears. With more than 37 per per cent of zinc, the β phase is stable at all temperatures down to 470 deg., and the slowly cooled alloys possess the duplex structure (Fig. 4), which is well seen in ordinary Muntz metal (40 per cent of zinc). Carpenter holds that below 470 deg. the β phase decomposes into α and γ phases; in fact, that β is an almost ultramicroscopic mixture of α and γ phases.[12]

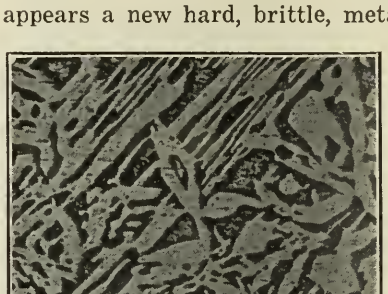

FIG. 4. HOT-ROLLED BRASS. ETCHED WITH DILUTE H_2SO_4 AND POTASSIUM DICHROMATE
A yellow β matrix and reddish α figures. After Rawdon. × 100.

Speaking of the γ phase of brass, Rosenhain (p. 145) says that it "is exceedingly hard and brittle and its presence in the alloys renders them useless for any purpose where strength and toughness are required. This is a typical example of a law very widely applicable to alloy—viz., that those phases of a binary system which contain the two elements in anything like equal proportions are hard and brittle, only the alloys near the ends of a series being as a rule sufficiently strong and ductile to be of practical ultility. We have already seen that the β phase is harder and more brittle than the α, so much so that the best brasses, in which strength and ductility are of importance, are generally made with a zinc content of approximately 30 per cent, this being the cheapest alloy which does not contain the β phase."

Von Weimarn[13] has shown that with solutions, medium concentrations are favorable to the development of relatively large crystals, whereas dilute solutions tend to yield colloidal dispersions; and in mixtures of two metals this seems to hold true also. The amorphous or colloidal phase of most metals is stronger at ordinary temperatures; and highly crystalline metal, deficient in amorphous or colloidal phase, is brittle because it tends to split along the lines of crystal cleavage. We should therefore expect brittleness where the component metals of a binary alloy are in about equal proportions, for this concentration hinders the development of colloidal metal and favors larger and more perfect crystals.

(Part IV, dealing with Iron and Steel, will appear in a subsequent issue.)

[9]The phase rule of Gibbs is postulated on the basis of the homogeneity of the phases involved. Within the colloidal zone, one or more of the phases become heterogeneous, in the sense of the phase rule, which is therefore no longer applicable.

[10]Obviously Rosenhain means homogeneous *to the microscope*, for all alloys are essentially heterogeneous.

[11]Rosenhain, "Introduction to Physical Metallurgy," p. 142.

[12]This means colloidal dispersion, favorable to hardness.

Low-Temperature Distillation of Amalgams of Non-Coking Coal and Asphaltic Oils*

By Joseph D. Davis† and C. E. Coleman‡

DURING some distillation experiments conducted by the Bureau of Mines in co-operation with the Trent Process Corporation[1] it was observed that amalgams[2] of heavy petroleum oils and finely pulverized coal tended to produce a denser coke than that obtainable from the coal when retorted alone. Even anthracite when retorted with oil yielded a coke. This led the writers to believe that by mixing a low rank coal—subbituminous or even lignite—with asphaltic oil, and retorting it, a coke suitable for domestic fuel could be made. Thus was contemplated production of domestic coke and utilization of a low-grade oil in one operation.

In order to decide on the practicability of this process it was necessary to know the value of products obtainable by such a method, as compared with those obtained by separate distillation. A laboratory method was therefore devised, and while it was realized that no small-scale testing apparatus for destructive distillation gives results that are directly applicable to commercial-scale operations, by keeping distillation conditions uniform for comparative tests, results were obtained valuable for purposes of comparison. The plan was to distill mixtures of coal and oil in a laboratory retort, and then distill the constituents separately under the same conditions. The comparative quantities of products yielded were thus directly obtained, and their quality was determined by analysis. The following are the main points investigated:

(1) Quantity and quality of coke; (2) quantity of oils boiling below 221 deg. C. (gasoline stock) and of oils boiling at 221 to 300 deg. C. (kerosene stock); and (3) quantity and quality of gases.

The apparatus used in these experiments has been described in a previous article. (Chemical & Metallurgical Engineering, vol. 25, p. 1132, Dec. 21, 1921.)

Materials Used

The coal used was a mixture of equal parts of Utah Standard lump and Utah King lump, both being non-coking coals. They were pulverized to 200 mesh, and a sample of the mixed product gave the following analysis:

	As Received Basis, Per Cent	Dry Basis, Per Cent
Moisture	3.43	.....
Volatile matter	44.92	46.52
Fixed carbon	45.62	47.24
Ash	6.03	6.24
	100.00	100.00

The oil used was Casmalia crude obtained from Santa Maria, Cal. It contained approximately 9 per cent water, and when dehydrated showed a specific gravity of 1.001 at 15 deg. C. It was a very viscous asphaltic base oil, and left a residue of approximately 15 per cent on distillation to dryness.

About 12 liters of hot water was added to 12 kg. of coal in a 20-gal. stoneware churn. After churning the mixture for 10 minutes, whereby the coal was thoroughly wetted, 5.1 kg. of oil was added. The mixture was now churned until the coal and oil agglomerated into little balls the size of a pea. The water was drained from the resulting amalgam, which was squeezed to remove inclosed water and allowed to air dry for several days before retorting.

TABLE I—YIELD OF DISTILLATION PRODUCTS

Yield Expressed as per Cent of Charge

Charge	Amalgam	Oil	Coal
Max. dis. temp., deg. C.	600	600	600
Water, per cent	14.0	7.0	10.6
Tar:			
Per cent	14.2	69.3	11.5
Sp. gr.	1.038	0.928	1.015
Gas:			
Per cent	17.0	4.5	10.1
Sp. gr.	0.5561	0.6185	0.5816
B.t.u.	820	966	726
Light oil from gas, per cent	8.1	4.0	3.2
Residue, per cent	40.1	15.2	60.3
Distillation loss, per cent	6.6	0.0	4.3

Yields per Ton of Amalgam

	Amalgam	Oil (670 lb.)	Coal (1,110 lb.)	Sum of Oil and Coal When Distilled Separately
Tar, gal.	32.8	60.9	15.2	76.1
Oils boiling 0 to 221 deg. C., gal.	9.9	9.0	4.1	13.1
Oils, boiling 221 to 300 deg. C., gal.	8.1	17.3	4.1	21.4
Gas, cu. ft.	7,450	668	2,500	3,168
Coke, lb.	802	103	660	763
Heating value of gas:				
B.t.u. per cu. ft.	820	966	726	777
B.t.u. per ton	6,109,000	645,288	1,815,000	2,460,288

Duplicate distillation runs were made with charges of oil, coal, and a mixture of the two. The charges, approximately 5 kg. in each case, were placed in the cold retort, and gradually heated to a temperature of 600 deg. C. The heating current was then regulated so as to maintain the temperature constant at this point until gas ceased to be evolved, when the test was considered finished. Coal and amalgam were charged directly into the retort, but it was necessary to use a welded sheet-iron container for the oil to prevent it from seeping through the clay baffle into the cold retort bottom and outside the constant temperature zone.

At the end of each test the coke was carefully removed from the retort and weighed, likewise the tars. In order to get the total tar yield, it was found necessary to weigh all parts of the condensing apparatus before and after each experiment.

Table I gives the average yields of distillation products in percentage of material charged, and also in quantities obtained per ton of amalgam. The yields for oil and coal were calculated from the separate distillation tests for quantities sufficient to make 1 ton of amalgam. The sums of yields for oil and coal are therefore comparable with those obtained for the amalgam.

The tar oils were first dehydrated in a 600-c.c. Barrett copper retort, which was heated over night in a Freas electric oven at 105 deg. C., the water and light oils distilling over being caught in a graduated separatory funnel. The water thus collected was measured and drawn off from the supernatant oils, which were returned to the retort. The dry tar was now fractionated from the copper retort, which was heated over a ring gas-burner so that the distillate collected at the rate of two drops per second. The amount of liquid collecting for each 25-deg. interval was noted and the results are given in Table II, together with fractions collected below 221 deg. C. and from 221 to 300 deg. C. These last-mentioned fractions were taken to represent gasoline stock and kerosene stock respectively.

Light oils absorbed in the charcoal scrubber were

Calculated heating value, B.t.u. per cu.ft.	820	726	966

with heating values calculated from the analysis in each case.

Discussion of Results

The results just described show that the amalgam yields more than twice as much gas as its constituents distilled separately, and less than half as much tar oil. The amalgam gas is richer than the combined gases from coal and oil by 43 B.t.u. per cu.ft., so that the total heating value in the gas from 1 ton of amalgam is 2.5 times that in the combined gases from the coal and oil. There was obtained from the amalgam 18 per cent more solid residue than from its constituents, and, while it was not as dense and firm as byproduct coke, it was far superior to the residue obtained from the coal. The latter was only loosely caked together, and could be easily crushed in the hand. The light oil scrubbed from the amalgam gas amounted to 4.4 gal. per ton of charge, and that from the constituents was 0.9 gal. per ton of charge. The oil from the amalgam gas was lighter than that from the coal gas; 42 per cent of the former boiled under 100 deg. C., compared with 22.6 per cent for the latter. There was not sufficient oil obtained from the gas of the oil distillations for analysis.

The main effect of mixing oil and coal previous to distillation under the conditions prevailing for these tests is to increase greatly the gas yield at the expense of the tar. The increase in gas doubtless comes from the oil. At least a part of the oil in an amalgam must be regarded as adsorbed oil, and under those conditions it would have an abnormally low vapor pressure, which would tend to hold it in contact with the coal at temperatures far above its normal boiling point. This would promote cracking or breaking up into simpler hydrocarbons. In this case, very light liquids and gaseous hydrocarbons were produced.

It is conceivable that the severity of the cracking reactions could be modified by distillation under reduced pressure, so that a high yield of light liquids at the expense of the gas might be obtained. Reduced pressure would certainly increase the yield of liquid products from that part of the oil not adsorbed by the coal.

Conclusions

Amalgams of a bituminous non-coking coal and a heavy asphaltic oil were distilled to a temperature of 600 deg. C., and the products were collected and examined. The method consisted of charging the material into a cold retort, slowly heating to 600 deg. C., and holding the temperature at this point until gas ceased to be evolved. Following distillation of amalgams, samples of the coal and oil used were distilled separately under the same conditions as those prevailing for the amalgam, the products in each case being collected and examined as before. On comparing the distillation products from the amalgam with the combined products for equivalent quantities of coal and oil distilled separately, the following conclusions were reached: Under the distillation conditions prevailing—

(1) The amalgam yields only about half as much tar oils as its constituents.

(2) A lower yield of gasoline and kerosene stock is obtained for the amalgam—9.9 and 8.1 gal. respectively per ton, as compared with 13.1 gal. and 21.4 gal. from the coal and oil.

(3) The residues obtained from the oil and coal were not coked; whereas that obtained from the amalgam was a coke of fair quality. The residue from the amalgam was 18 per cent greater than the combined residue from coal and oil.

(4) The amalgam yields over twice as much gas as the coal and oil distilled separately and its heating value is 5 per cent higher. The total heating value of gases from one ton of amalgam was 6,109,000 B.t.u. against 2,460,288 B.t.u. for the combined gases from coal and oil.

Potash Salts of Western Texas

By George Steiger

THE possibility that a workable deposit of potash exists in western Texas is shown by the co-operative work of the United States Geological Survey and the Bureau of Economic Geology and Technology of the University of Texas. Samples of salts brought to the surface by the bailer, during the routine drilling of wells being bored for oil in this region, have been analyzed and if truly representative of beds of any considerable extent and thickness they contain sufficient potash to be of industrial value. Careful consideration, however, must be given the specimens, as these samples were from wells being drilled for oil and not potash, and while not intended to be in any way pessimistic, the object of the first part of this paper is to describe conditions under which samples were collected and to point out some of the pitfalls in the path of those drawing too hasty conclusions from the samples already analyzed.

Conditions of Sampling Not Recorded

Oil being the objective and not the soluble salts, no record was kept, so far as known in the Geological Survey, of the quantity of water in the wells or the length of time it may have been in contact with the salts. Neither are any data available concerning casing used, consequently no conclusions could be drawn regarding the possible contamination due to material falling in from higher levels, and only a vague guess could be made as to what extent the potash content of the samples assayed may have been changed by the action of water. Also it is not known whether the entire amount of material supposed to have come from the section in question had been carefully sampled or a grab-sample taken from a single bailerful.

Concentration by Loss of More Soluble Salts

The samples as received were in fragments approximating in size cracked corn. Had water played the part of dissolving the more soluble salts, the remaining fragments would be expected to show certain characteristics. Fragments of salt only partly dissolved would probably be found with rounded edges. On the other hand, sharp edges on angular fragments might be accounted for by assuming the presence of water in volume sufficiently large to dissolve quickly all salts, including polyhalite, shortly after being torn loose by the drill.

Under the latter condition a sample would represent material through which the drill had passed immediately before bailing. Many of the samples examined contained well-rounded grains of sodium chloride, and, as might be expected, the angular structure of the fragments of polyhalite and anhydrite had been more perfectly preserved.

Potash Present Largely as Polyhalite

A number of samples chemically tested showed in every case the potash to be present entirely in the form of polyhalite, and a visual inspection of many more showed this mineral invariably present in the richer salts. With our present knowledge it cannot be positively stated that polyhalite is the only form in which potash is present in these salts, but it certainly occurs largely as this mineral.

Polyhalite, when treated with a quantity of water insufficient to dissolve all the calium sulphate, leaves a deposit of easily recognizable gypsum.[1] Small quantities of gypsum were found in some of the samples, but the majority of them contained the calcium sulphate in the form of anhydrite.

If these salts had been exposed to the action of water with violent agitation, polyhalite, being rather less soluble than the other commonly occurring salts, could easily have been concentrated. On the other hand, had potash been present in one of its more soluble salts such as sylvite, it would have been dissolved along with the sodium chloride and thus compensate or possibly overbalance the concentration due to polyhalite.

Intensive Study Required

So many unknown factors must be taken into consideration that it is extremely doubtful just what the samples available at the present time represent. It might be that the drill has passed through one or more beds several feet in thickness of potash-rich salts; again, none of them may be more than a few inches in thickness. One thing we do know is that polyhalite has been laid down in the massive form and practically pure, and it seems reasonable to assume that somewhere in the vast salt deposits of this region beds sufficiently thick to be worked economically will be found. In order to locate such beds, if they do exist, core drilling must be resorted to. Meanwhile parties drilling for oil are showing more interest in the possible potash value of their wells and some of the samples recently submitted for assay are accompanied by more carefully taken data. An intensive study made at the wells now drilling will be rewarded certainly with a better knowledge of the extent and thickness of the potash-rich beds and possibly with data upon which industrial development can be based.

Polyhalite, as it occurs in these salts, is light red to gray in color, compact with a fairly granular structure, and practically without taste. It so closely resembles in its properties the anhydrite, which is abundant, that it is not possible to distinguish between the two minerals without resorting to chemical or optical tests.

Factors Influencing Interpretation of Analytical Results

In the analysis of these salts, a point which deserves special attention is the necessity for stating the ratio of salt to the water used for solution. In the method used by the Geological Survey, 5 g. of the salts is boiled with slightly less than 500 c.c. of water, the solution cooled and made up to 500 c.c. The ratio of 1 : 100 was arbitrarily taken. If these salts become of industrial importance it may be advisable to adopt a ratio in their analysis more nearly agreeing with that used in their commercial extraction. The necessity of stating the quantity of water used in dissolving these salts for analysis is clearly brought out when the analysis of pure polyhalite is considered. One gram of polyhalite contains 0.452 g. $CaSO_4$, 0.199 g. $MgSO_4$, 0.289 g. K_2SO_4 and 0.060 g. of water. While the presence of other salts will slightly change the figures, 100 c.c. of pure water is capable of dissolving at 25 deg C. 0.208 g. of $CaSO_4$.

[1] A notation made by R. C. Wells in the course of routine assays.

This dissolved $CaSO_4$ added to the easily soluble $MgSO_4$ and K_2SO_4 in 1 g. of the mineral will total 0.696 g. or 69.6 per cent of soluble salts. By calculation we find that the 15.6 per cent of K_2O in polyhalite becomes 22.4 per cent of K_2O in the soluble salts. This figure will vary accordingly if a larger or smaller amount of water is used.

An actual analysis made by R. K. Bailey of pure polyhalite separated from salts that were taken from the McDowell well gave the following results: soluble salts 69.9 per cent, K_2O 15.10 per cent, which is equivalent to 21.7 per cent of K_2O in the soluble salts. These figures agree with theory within the limits or error in manipulation.

Analyses of some of the richest salts are given in Table I, the location of the wells being as follows: Bryant well, 9 miles south of Midland, Tex.; Burns well of the La Mesa Oil and Gas Co., 16 miles east of La Mesa, Tex.; Pitts Oil Co.'s well, 8 miles east of Barstow, Tex.; Means well, Loving County, Tex.

TABLE 1—ANALYSES OF SOME OF THE RICHEST SALTS

1,610-1,614	66.54	5.60	8.42	2.58
1,645	40.32	4.23	10.50	1.94
1,695-1,700	55.42	6.29	11.35	3.02
1,700-1,704	43.46	2.49	5.74	1.30
1,875	53.60	5.65	10.54	2.72

*R. C. Wells, analyst. †George Steiger, analyst. Remainder, R. K. Bailey, analyst.

MgO found in the six samples from the Pitts well is lightly more than the polyhalite ratio would require to combine for combination with K_2O found in the respective samples.

Selected Sample Checks With Polyhalite

One sample of rather roughly separated red salt from the Pitts well gave on analysis 13.74 per cent K_2O, while a specimen in a single lump weighing 75 g. contained 11.50 per cent of K_2O. A small sample very carefully separated from salts taken from the Bryant well had the following composition:

	75 g. Lump	Theoretical, Polyhalite
CaO	18.14	18.6
MgO	7.05	6.6
K_2O	15.63	15.6
Na_2O	2.06	...
H_2O	6.13	6.0
R_2O_3	0.35	...
Insoluble	0.22	...
SO_3	Not det.	53.2

Sufficient material was not available for the determination of SO_3. For comparison the composition of pure polyhalite is given in column 2.

Chemical Laboratory,
U. S. Geological Survey.

Export Trade of Switzerland

An interesting summary of Switzerland's foreign trade is given in a recent issue of the *Swiss Exporter.* Up to 1919, Germany was the principal purchaser of Swiss goods, but at that time the various import restrictions of 1920, together with the depreciation of currency rates, relegated her to the fourth rank of markets for Swiss goods. England, which had been third in the list of consumers of Swiss goods up to 1920, now took first place. The increasing difficulties of exporting goods to countries with low rates of exchange makes the exportation of Swiss goods to Great Britain, the Dominions and Colonies an important factor. The total exports to the British Empire amounted in 1920 to 914,000,000 fr., or almost 28 per cent of the total Swiss export trade. This is nearly triple the figure for 1913, while the exports of the British Empire to Switzerland increased more than 3¼ times.

The second place among customers of Swiss industries has been occupied by France since 1915, that country taking one-sixth of the total of Swiss exports. The value of machinery exported to France in 1920 reached the sum of 104,500,000 fr. or 35 per cent of the total exports of Swiss machinery.

The goods imported by Switzerland from the United States in 1920 totaled 865,000,000 fr., as compared with exports to this country of one-third that figure.

The exports of coal-tar dyes and synthetic indigo from Switzerland have increased sevenfold since 1913 and total 211,000,000 fr. for 1920. The principal markets during this year were Great Britain with 62,750,000 fr., France 49,200,000 fr., U. S. 16,000,000 fr., Belgium 15,500,000 fr., Italy 10,700,000 fr., South America 8,000,000 fr., and Japan and China 6,500,000 fr. The Swiss coal-tar dye industry goes back to the year 1856 and has its headquarters at Basel. Another important branch of the Swiss chemical industry is that of pharmaceutical products, which is also centered at Basel. The export returns of pharmaceutical products for Switzerland in 1920 totaled 32,000,000 fr., of which 19,000,000 fr. was for vegetable extracts, powders, pastilles, etc., 11,700,000 fr. for alkaloids and 11,100,000 for other remedies, mainly synthetic.

Of recent years there has been great progress in the exports of saccharine from Switzerland and of perfumery, mostly in concentrated form. Recently the manufacture of photochemical preparations has been taken up with considerable success.

Russian Soviet Organizes Production and Sales of Platinum

Commerce Reports of Dec. 26, 1921, reports the organization of a state-controlled "platinum trust" by the the Soviet Government which will have charge of all the platinum prospecting and mining business in Siberia, as well as the platinum smelting and refining works near Petrograd, Moscow and Ekaterinburg. This trust will act as the central sales agency for both foreign and domestic trade, and will thus be in a position to regulate the prices of platinum in the international market.

The total production for 1921 up to August was about 6,000 troy ounces. The annual average production for 5 years prior to 1914 was 172,000 troy ounces. After the beginning of the World War the output of Russia's platinum mines showed a steady decline, production coming to a complete standstill about the middle of 1918.

Fullers Earth Deposit at Olmstead, Ill.

By Cullen W. Parmelee
Professor of Ceramic Engineering, University of Illinois

THE purchase by the Standard Oil Company of Indiana of a considerable tract of land at Caledonia, near Olmstead, Ill., during the past summer has directed attention to the large deposit of fullers earth there.

The discovery of this deposit dates back to about 1912, when H. J. Gardner, then connected with the Kentucky Geological Survey, visited the bluffs on the Illinois side of the Ohio River during the course of his professional studies. Prior to that time Mr. Gardner had met C. C. Ruprecht, who had had considerable experience with fullers earth generally and the Florida deposits in particular. As a sequel of that chance meeting Mr. Gardner's interest in fullers earth had been aroused and noting the peculiar character of the deposit outcropping in the river bluffs, he sent samples to Mr. Ruprecht. Thus, by a fortunate chance, the material was brought to the attention of an expert well qualified to recognize its value and well equipped to devise means for the proper development of the deposit.

Since the raw material proved to be dissimilar to the Florida earth and to have a rather low efficiency, Mr. Ruprecht spent considerable time in devising a suitable process for its improvement. His efforts were finally crowned with success and he and his associates obtained options on the land. In order to demonstrate the value of the earth, the Illinois Fuller Earth Co. was organized, a mill was erected and the prepared earth was marketed.

The mill has been in successful operation for more than a year, and during most of that time it has been running steadily day and night. The Sinclair Refining Co. of Chicago has now taken over the mill and 55 acres of land. In August the Standard Oil Company of Indiana purchased, according to press reports, 155 acres of land, for which $23,512.50 was paid, and Mr. Ruprecht and his associates received $100,000 for their patents and rights to processes for the treatment of the earth.

Fullers earth is a variety of clay which has the peculiar property of possessing high absorbent power due to its high colloid content. Formerly it was imported chiefly from England, but a few years ago deposits of suitable material were found in Florida and adjacent parts of Georgia. Since then deposits have been located in other states, so that in 1920 the following were reported by the U. S. Geological Survey in the order of their rank as the producing states: Florida, Georgia, Texas, Alabama, Nevada, Arkansas, California and Massachusetts. The total quantity of material produced in 1920 was 128,487 tons, valued at $2,506,189. During the same period 19,235 tons valued at $221,893 was imported.

FIG. 1—FULLERS EARTH DEPOSIT AT OLMSTEAD, ILL.

Working the Deposit at Olmstead

The most important use of fullers earth is in the bleaching of mineral, animal and vegetable oils. Other applications are the removal of grease from cloth and in the preparation of soap.

The deposit at Caledonia Landing, as the riverfront at Olmstead is called, belongs to the Midway Formation of the Tertiary System. As already stated, it appears as a bluff about 112 ft. high extending along the shore of the river for about 2 miles. The pit of the Sinclair Refining Co. is situated about 500 ft. back from the river.

The earth is being dug in an open pit (Fig. 1), which covers an area of about 2 acres. The overburden of 10 ft. of sand and loam is loosened by shooting and then removed in wheelbarrows. Below this there is a working face of 34 ft. which is the best quality fullers earth. The earth presents a distinctly jointed structure and is readily dislodged by prying with bars and shooting. Below this face there is 30 ft. of an inferior grade of earth which has only about 80 per cent of the efficiency of the upper portion. The earth thus loosened is loaded into small cars, which are hoisted by cable on an inclined track and dumped into a receiving bin at the factory.

Preparing the Fullers Earth for Market

As the raw material comes out of the pit it is in the form of large lumps of a dark brown color having a fair degree of hardness. These are reduced to cubes of 1 in. size by crushing with differential rolls having breaker bars on one roll. These small lumps are fed into a rotary oil-burning direct-flame drier 20 ft. long and 3 ft. in diameter. The maximum temperature reached in this drier is 900 deg. F. The earth passes through this drier in 12 minutes, and during its travel the water content is decreased to 3 to 5 per cent. This is accompanied by a brisk reduction in the size of the lumps due to the popping caused by the rapid removal of the water content. Further crushing is done in a "hummer" mill, where the grain is reduced to pass 10 mesh. The pulverized material is elevated and passed over inclined screens which are electrically vibrated. Three grades are separated: The 16-30 mesh, for the bleaching and filtration of mineral oil; the 30-60 mesh, for the same purpose; the 60-300 mesh, for filtering lard, vegetable oils, soap stock, etc.

The screened dry material is sacked and is then ready for shipment. It is very hygroscopic and takes up about 12 per cent of water during storage and shipping.

The plant has a capacity of about 350 tons per month.

It is reported that the Standard Oil Co. is to erect a plant of about the same capacity as the one described and that another oil company is interested.

Mr. Ruprecht estimates the total amount of fullers earth available as 4,000,000 tons.

The central location of this deposit with reference to the mineral and vegetable oil refineries, its easy accessibility by water and rail and the great quantity of the raw material will make Illinois one of the important producers.

Stability of Conducting Electric Furnace Hearths

By Frank Hodson

THE increasing interest that is now being shown in the use of electric furnaces for melting up iron borings and cheap scrap and also in the use of large-capacity electric furnaces for refining hot metal again brings to the fore the advisability of intending furnace users considering the many advantages of furnaces having a properly designed and proved bottom connection.

In the Greaves-Etchells furnace, as will be seen from the illustration, two phases of the three-phase power are taken through top electrodes and the third phase is connected directly to a copper plate lying underneath the lining, giving a definite source of power under the charge. No studs project into the lining and after putting a few inches of special carbon compound over the copper plate, the whole lining is rammed in of standard basic material—dolomite or magnesite, or mixtures of the two mixed with sufficient tar to bind. The lining is purposely made thick and highly resistive at the upper part where it is in contact with the charge. It is here the heat is generated by resistance, not in the copper plate, which always is cool enough to touch. In drying out the lining, the tar, before being burned out, helps to carry

GREAVES-ETCHELLS FURNACE
Dotted lines indicate tilting position

the current through and, once current has been put through, will continue to carry current. If the lining is kept reasonably free from slag or silicon from the roof, the furnaces will start up cold with the bottom functioning normally. In any case, even with a cold furnace, only a very few minutes suffice to get bottom connection. When it is obtained, the advantages are very pronounced. In addition to the top arcs considerable heat is generated in the charge by its resistance to the flow of current—more heat is generated by the resistance of the surface of the hearth and this is immediately absorbed by the charge in contact with the lining.

The charge comes down very evenly without the mechanical stirring or danger of burning the bottom, as when the electrodes of a top-connected furnace bore through the scrap. When molten, the heat generated under the charge keeps it moving slowly upward. This slow circulation from the bottom can be seen and has many times been proved. Temperature of metal at different depths in the bath, analysis of alloy steels at different depths, all prove that slow circulation does exist. In the refining of either iron or steel, this circulation not only carries away and usefully absorbs the intense top heat of the arcs, but also brings all parts of the bath into contact with the refining slags. Sulphur or phosphorus refining and deoxidizing are therefore very rapid and thorough.

The linings are usually constructed with a depth of solid basic refractory from 20 to 30 in., depending on the size of the furnace. As the heat generated at the top of the furnace lining is always absorbed as rapidly as made by the charge, there is no danger of weakening it. The metal comes out clean—a skull on the furnace hearth is practically unknown—no segregation of alloys on the bottom and no thickening up.

Over seventy furnaces with this resistive durable hearth are now in successful operation. A Greaves-Etchells furnace installed in June, 1917, has worked continuously with the production of thousands of casts and is still in operation on the original hearth. In one of the large works here the practice is followed of chipping out about 4 or 5 in. of the top surface of the hearths once a month and re-ramming new material in. This is done more as a metallurgical precaution to insure clean steel, but the real linings of these furnaces have not been changed for years. There is no doubt that a hearth of this type, having very distinct metallurgical and electrical advantages, when intelligently installed and maintained is practically permanent.

Dry-Cell Standards Proposed

FEWER sizes and revised specifications for dry cells will result, it is expected, from the recommendations of the Bureau of Standards on dry cells and dry-cell batteries. These recommendations are those drafted by the conference held at the bureau early in December, when representatives of manufacturers, commercial users and government department users met to plan for simplification and increased efficiency in this industry.

Sizes of Dry Cells

The conference considered first the different sizes of dry cells which are now being made. These included seventeen different sizes. As a result of the discussion, six sizes were adopted as standard, one additional size being included provisionally. The members requested the Bureau of Standards to take up the question of tolerances in the dimensions for these cells, and the bureau, therefore, in submitting this report calls attention to the fact that the exact dimensions of the cells and batteries as given in the following tables are subject to revision. The bureau invites criticisms of the dimensions and asks that the manufacturers furnish data for fixing the tolerances. The sizes of dry cells adopted as standard by the conference are shown in Table I.

Several other sizes of cell were considered to be of some importance, but not sufficiently so to be included in the standard list. These are the No. 8 cell 3½ x 8 in. for

TABLE I—SIZES OF DRY CELLS

Designation	Diameter of Zinc Can, Inches	Height of Zinc Can, Inches	Height Over All, Inches	Diameter Over Carton, Inches
No. 6	2½	6	6½	2⅝
No. 4	1½	4	4⅜	1⅝
Flashlight	⅝	1⅞	2	..
Flashlight*	¾	2¼	2¼	..
Flashlight	1 5/16	1 13/16	1⅞	..
Flashlight	1¼	2½	2⅝	..
Flashlight	1¼	2⅞	3	..

*Provisionally adopted; the use for this cell is decreasing and it probab'y will not be continued long as a standard size of cell; used in third battery of Table II.

export; a flashlight cell 9/16 x 1⅞ in. for small tubular flashlights; the cell 1 x 2⅞ commonly used in earphone batteries; and a flashlight cell 1¼ x 3½ in. which may become an important cell in the future.

Flashlight Batteries

The conference next considered thirty different sizes and kinds of flashlight batteries and adopted eight of

TABLE II—STANDARDIZED SIZES OF FLASHLIGHT BATTERIES

Assembly	No. Cells	Size of Cell — Diameter, In.	Size of Cell — Height, In.	Size of Battery — Length or Height, In.	Size of Battery — Width or Diameter, In.	Size of Battery — Depth, In.
Flat	2	⅝	1⅞	2½	1 5/16	11/16
Flat	3	⅝	1⅞	2¼	1 13/16	11/16
Flat	3	¾	2¼	2⅝	2 1/16	13/16
Tubular	2	13/16	1 13/16	3¾	1	....
Unit cell	1	1¼	2½	..	....	....
Tubular	2	1¼	2½	4 11/16	1 5/16	....
Tubular	3	1¼	2½	7	1 1/16	....
Box	3	1¼	2⅞	3	3⅛	1⅜

these as standard sizes. These standard sizes are shown in Table II.

The conference next considered batteries containing fifteen cells for radio use, and standardized two sizes of these batteries as shown in Table III.

TABLE III—BATTERIES FOR RADIO USE

Assembly	No. Cells	Size of Cell — Diam., In.	Size of Cell — Height, In.	Dimensions of Battery — Length, In.	Width, In.	Height, In.
Rectangular box	15	⅝	7/8	3¾	2	2½
Rectangular box	15	1½	2½	6⅝	4	3

The conference also considered batteries assembled from cells of the No. 6 size and selected from about

TABLE IV—ASSEMBLED BATTERIES

Assembly	Voltage	Length, In.	Width, In.	Height, In.
0000	6	10½	2¾	7½
00 | 00 ∫	6	5¼	5⅜	7½

000 | 00 ∫	7½	7⅜	6¾	7½
000 | 000 ∫	9	7¾	5⅜	7½
00	3	5¾	2¾	7½

thirty different sizes and arrangements those in Table IV as standard.

Tests for Dry Cells and Batteries

The matter of tests for dry cells and batteries was discussed at length and the following conclusions reached: The test which has been commonly referred to as the A. T. & T. test is to be known in the future as the "light intermittent service test."

In the discussion of this test the fact was brought out that the resistance of the telephone circuit is more nearly 50 ohms than 20 ohms and that a 50-ohm test (as well as a 20-ohm test) is in use by the American Telephone & Telegraph Co. It was the opinion of the conference, however, that the characteristics of the cells are properly shown by the 20-ohm test which has been used in the past and the 20-ohm test should be contained as standard, since the 50-ohm test requires too much time to complete. The ignition test is to be known as the "heavy intermittent service test." The reasons for changing the name by which this test and the telephone test are designated were first that: the names "telephone" and "ignition" imply too limited an application of these tests, and second that the duration of the test is a more important factor than the current intermittently discharged. The heavy service intermittent test was modified by specifying a cut-off voltage rather than the impulse current which has previously been employed to define the end of the test. The cut-off voltage adopted was 0.85 v. per cell. The 10-ohm continuous test for large cells, the 2.75-ohm test for flashlight cells and the flashlight intermittent test were continued as in the past. As a standard test for the radio batteries of fifteen cells each, the conference adopted a continuous discharge through 5,000 ohms to a cut-off voltage of 17 v. for the battery of 1.13 v. per cell.

The conference considered the significance of the short-circuit current test and adopted a motion that this test should not be applied to telephone cells. The bureau was asked to investigate further the significance of the short circuit current test.

Work in Progress

The conference instructed the bureau (*a*) to obtain information from the manufacturers as to tolerances in the dimensions for each size of cell or battery, (*b*) to prepare specifications for delayed service tests of 3, 6, 9 and 12 months, (*c*) to revise the specifications which are contained in circular 79 of the Bureau of Standards, and (*d*) to take up with the earphone manufacturers the possibility of reaching an agreement on standard sizes of batteries for earphones.

In several cases the conference was unable to fix the required performance of certain sizes of cells on test and the matter is to be decided as a result of additional tests to be made on samples submitted to the Bureau of Standards by the manufacturers. Changes in the required performance of flashlight cells and batteries as recommended to the conference by the Bureau of Standards were adopted.

Several times during the discussion mention was made of the possibility of future conferences. No formal action was taken in this matter, but the bureau welcomes the suggestion, and will be glad to do its part in making future revisions and in maintaining the effectiveness of the standardization.

First Aid Treatment for CO Poisoning

The Bureau of Mines has recently issued a report of investigations on the treatment of carbon monoxide poisoning. Although a frequent cause of industrial accidents, there appears to be no uniformly recognized treatment for a person overcome by this gas. The treatment recommended by the bureau is as follows:

1. Administer oxygen as quickly as possible and in as pure a form as is obtainable, preferably from a cylinder of oxygen through an inhalator mask.
2. Remove from atmosphere containing CO.
3. If breathing is feeble, at once start artificial respiration by the prone pressure method.
4. Keep the victim flat, quiet and warm.
5. Afterward give plenty of rest.

Synopsis of Recent Chemical & Metallurgical Literature

Graphitization of White Iron.—In a paper "On Graphitization in Iron-Carbon Alloys"[1] Kotaro Honda and Takejiro Murakami present some new experimental results and a novel theory of the mechanism of graphitization.

For all experiments a white iron of the following composition was used:

	Per Cent		Per Cent
Carbon	3.75	Phosphorus	0.043
Silicon	0.063	Sulphur	0.01
Manganese	0.091		

This material was melted in a small alumina tube heated in a platinum-wound resistance furnace. Temperature measurements were made with a platinum-platinum rhodium thermocouple in a thin silica protecting tube dipped in the molten metal. Analyses made in some of the experiments showed the absorption of silicon by the metal to be less than 0.03 per cent, an amount which the authors consider too small to affect the graphitization. Weight of metal used in each experiment was 20 g., and the degree of graphitization was estimated by microscopic observation, analyses being reported in only a few cases.

Period of Graphite Formation

The stage at which graphite is formed during cooling was determined by quenching experiments. Having determined certain conditions of heating and cooling which would result in graphitization, melts were allowed to cool to various temperatures and were then quenched in water. No graphite was observable after quenching at the eutectic temperature (1,130 deg. C.), a temperature determined by the eutectic arrest in the cooling curve of the specimen. As the quenching temperature fell to 1,100 deg C. a small amount of graphite was produced, and when the quenching was done below 1,050 deg. C., the amount of graphite was nearly equal to that found after moderately slow cooling to room temperature. It was therefore concluded that graphite does not separate directly from the melt, but forms after solidification and largely between 1,130 to 1,050 deg. C.

Rapid cooling from the molten state produced white iron free from graphite even when the carbon content was raised by addition to almost the composition of cementite. In highly carburized alloys (hypereutectic) cooled somewhat slowly from 1,500 deg. C. two forms of graphite were observed—large straight plates and small curved flakes, as shown in Fig. 1. If the slow cooling was interrupted by quenching at 1,150 deg. C., the large plates were found, but the small flakes were absent. This result is seen in Fig. 2. The large plates are therefore held to be formed from primary cementite above the eutectic temperature, but the smaller flakes from ledeburite (the austenite-cementite eutectic) below this temperature. Fig. 3 shows the structure of a hypereutectic specimen cast at 1,500 deg. C. in an iron mold. It will be noted that the distribution of the primary cementite is similar to that of the large graphite plates in Fig. 1. The whole structure is on a smaller scale because of the more rapid solidification. A general conclusion that may be drawn regarding the period of graphite formation is that graphitization does not take place unless solid cementite is present.

[1] "On Graphitization in Iron-Carbon Alloys," K. Honda and T. Murakami, *Sci. Rep.*, Tohoku Imperial University, vol. 10, No. 4, September, 1921, p. 273.

Annealing of White Iron

It was found that the white pig iron used in this research always graphitized on annealing at temperatures above 1,000 deg. C. The graphite produced at such high annealing temperatures is flaky in form as distinguished from the rounded form found in malleable castings. The authors do not discuss the equilibrium relations of iron, graphite and cementite below the eutectic temperature nor do they report experiments bearing on this phase of the subject.

Mechanism of Graphitization

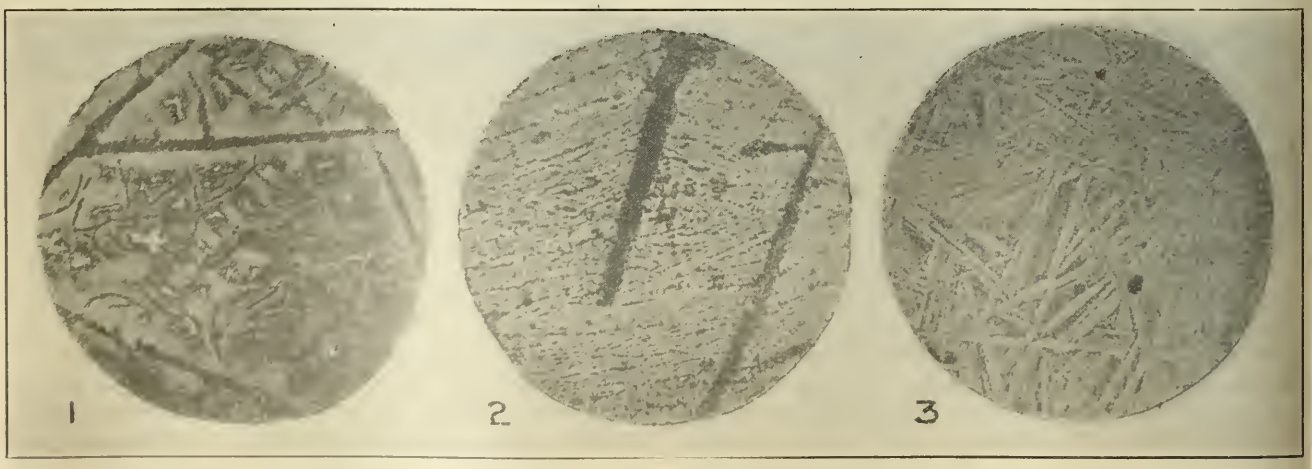
There are, according to the authors, two theories of the mechanism of graphitization: (1) the graphite is considered as a product directly separated from the melt; and (2) it is a secondary product formed by the decomposition of solid cementite, according to the equation

$$Fe_3C = 3Fe + C$$

The first theory is untenable in view of the quenching experiments which show that the graphite found in the solid alloy is formed only after solidification.

The authors also reject Howe's explanation, published in his "Metallography of Steel and Cast Iron," that graphite is less soluble in austenite than is cementite, being a more stable phase than the latter, and hence if there is a nucleus of graphite in austenite which is saturated with carbon, graphite is deposited on it, and the solution, becoming unsaturated with carbon, dissolves cementite.

In some of their experiments the authors dipped a graphite rod into the melt and found that the graphite formed during cooling appeared in other regions to a greater degree than at the surface in contact with the graphite rod. They also found that graphitization brought about by annealing did not appear to affect the extent of graphitization on remelting and cooling. From these observations they conclude that the nucleus theory is not probable. A final argument is given as follows:



FIGS. 1 TO 3.

Fig. 1. Straight and curved graphite flakes in high-carbon iron cooled somewhat slowly from 1,500 deg. C. × 80.

Fig. 2. Suppression of curved flakes by quenching from 1,150 deg. C. × 80.

Fig. 3. High-carbon iron cast at 1,500 deg. C. in an iron mold. × 100.

"According to the modern view of crystal structures based on the X-ray analysis, the atoms forming the molecules of a substance are separately arranged in the space-lattice of the crystal. A solid solution of carbon in iron has of course a crystalline structure, and therefore carbon atoms are uniformly distributed among iron atoms in the space-lattice. In the case of the solid solution of cementite in iron, carbon atoms must also be uniformly distributed among iron atoms. Since the crystal system is the same in these two cases and also iron and carbon atoms exert their own molecular forces on each other, the distributions of the atoms will very probably be the same in the two cases. If they were different, we must assume two modifications of austenite; but such modifications are not yet known. Hence there can be no difference between the solid solutions of carbon and cementite in iron and it is rather more correct to say that carbon dissolves in iron as solid solution. The above explanation as given by Prof. Howe is then untenable from the standpoint of the X-ray analysis of crystal structure."

Having thus dismissed the older explanations, the authors advance the hypothesis that graphitization is brought about by a catalytic action of carbon monoxide and dioxide according to these equations:

$$2CO = CO_2 + C$$
$$Fe_3C + CO_2 = 2CO + 3Fe$$

Thus graphite is produced by the decomposition of carbon monoxide which is regenerated from the carbon dioxide by reduction with Fe_3C. The process continues as long as the supply of cementite and gases holds out.

The evidence upon which this theory is based may be indicated as follows:

1. For a given rate of cooling, the extent of graphitization is less the higher the maximum temperature of the melt and the longer the time of exposure at this temperature. In metal heated to 1,200 deg. C., for example, and cooled at an average rate of about 12 deg. C. per minute, graphitization was about three-fifths complete regardless of the time of exposure of the melt. When the maximum temperature was 1,300 deg. C., the degree of graphitization diminished as the time of exposure increased, and no graphite was observable in specimens exposed at that temperature longer than 10 minutes. With a maximum temperature of 1,400 deg. C., no graphitization took place during cooling irrespective of the time of exposure. It was also found that the graphitization brought about by annealing was less in specimens previously heated at the higher temperatures. These facts are attributed to the decrease of the solubility of gases in the melt with rise of temperature.

2. Graphitization was found to be favored by the introduction of carbon monoxide, carbon dioxide, air or iron oxide into the melt. If the melt was exposed for some time after the addition of the oxygen-containing material, the graphitization became very small. No effect was obtained from passing hydrogen or nitrogen through the melt. These facts are also explained by the gas reaction theory.

3. The effect of air on graphitization was larger than that of carbon monoxide or dioxide. This is attributed to the formation of iron oxide which is supposed to remain in the metal and produce carbon monoxide more effectively than the direct addition of the gas.

4. If the pig iron was melted at 1,200 deg. C. and cooled at about 12 deg. C. per hour, graphitization took place. This treatment did not result in graphitization, however, if the iron was previously melted at 1,400 deg. C. and cast into an iron mold. This is consistent with the supposition that the heating at 1,400 deg. C. drove off the greater part of the carbon monoxide.

5. It was observed that graphite begins to develop from blowholes and cavities, which are regarded as containing the carbon monoxide or dioxide responsible for graphitization. The authors also found no graphite in metal cooled from the molten state in a vacuum unless the cooling was very slow.

6. In some specimens isolated spots were observed in which graphitization was complete. "The gas, which is initially found in their centers, diffuses outward, and owing to its catalytic action, graphitization takes place in spherical forms. The catalytic action gradually diminishes, as a definite amount of the gas is always distributed in an increasing surface, till the action ceases altogether when the gas density on the surface is reduced to a certain low value, or when the temperature becomes two low for graphitization."

7. The authors found that the ledeburite of hypereutectic iron graphitizes more readily than that of hypoeutectic irons. They consider that this is due to "an ample amount of free gases entered in the melt during the process of carburization by carbon powder."

Nature of Graphite Flakes

The authors disagree with the view of some metallurgists that the flakes are a form of graphite crystal, and hold that they are merely aggregates of fine graphite particles which take their form from the decomposed cementite crystals. They state that continued heating at high temperatures causes a rounding of the sharp corners of the flakes due to the surface tension of the austenite.

Magnetic Analysis[2]

The progress of graphitization can be followed by magnetic analysis. As the graphitization increases, the intensity of magnetization due to the cementite will decrease, but the total intensity will increase, owing to the formation of free iron. As the period of annealing increases (and hence the amount of graphite), the intensity of magnetization at room temperature gradually increases and the cementite transformation at 200 deg. C. decreases in magnitude. The ratio of the increase of deflection due to cementite to the total deflection at room temperature is taken as approximately proportional to the quantity of cementite undecomposed.

Some curves are given showing the rate of graphitization on annealing, as estimated by this method.

Dissociation of Ferric Oxide Dissolved in Glass.—In a paper read before the joint meeting of the Glass Division of the American Ceramic Society and the English Society of Glass Technology and published in the November *Journal* of the American Ceramic Society, J. H. Hostetter and H. S. Roberts describe the results of work on the dissociation of ferric oxide dissolved in glass and its relation to the color of iron-bearing glasses. It was shown that above 1,300 deg. C., Fe_2O_3 is dissociated appreciably with evolution of O_2 and the formation of the corresponding quantities of FeO. The same reaction is found to take the place in glasses. The following percentages of Fe as FeO based on the total Fe present illustrate the extent of this dissociation in glasses: Diopside glass ($CaSiO_3MgSiO_3$), 1,400 deg. C., 20 per cent; 1,500 deg. C. 30 per cent; 1,600 deg. C., 45 per cent. Glass having the composition $0.6K_2O$—$0.4CaO$—$2SiO_2$, 1,310 deg. C., 5.8 per cent; 1,555 deg. C., 10.1 per cent. Glass having the composition $0.3K_2O$—$0.3Na_2O$—$0.4CaO$—$2SiO_2$, 1,020 deg. C. 4.1 per cent. In the two latter glasses a dissociation of 10 per cent produced a bright green color; the glass with a dissociation of 4.1 per cent was yellow. Iron compounds in a glass may therefore be "reduced" by heating to a high temperature under oxidizing conditions. The intensity of the color due to iron is closely related to the composition of the glass, but data on this point are not sufficiently complete to warrant generalization.

Glaze Hardness on White Ware.—George Blumenthal, Jr., described in the November *Journal* of the American Ceramic Society the results of experiments conducted at the U. S. Bureau of Standards on the hardness of glazes for white ware and table porcelain. The enamels show the lowest and the porcelain glazes the greatest hardness, while the white ware glazes occupy an intermediate position. The difference in hardness between the enamels and the white ware glazes is quite marked. There is also a rather well-defined difference between the white ware and porcelain glazes, but not a sharp separation between the lower and higher fired porcelain glazes. Enough evidence has been accumulated to show that increased firing of the same glaze will increase the hardness. It appears also that increase in the alumina content brings about greater hardness.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Improvement of Patent Office Situation in Sight as House Passes Relief Bill

Despite the opposition of such influential members as Majority Leader Mondell and Chairman Madden of the Appropriations Committee, the House passed without amendment the Patent Office relief bill by the overwhelming vote of 305 to 44. The Senate Committee on Patents expects to consider the bill immediately and it is known that a majority favors reporting the bill to the Senate on the earliest possible date.

The opposition to the bill was based largely on the ground that increases in salary, in some cases amounting to as much as 50 per cent, are being allowed to one group of employees. If the same salary scale were applied to the 300,000 other employees of the government, outside the postal service, it would mean a tremendous increase in the federal expenditure.

The main three features of the bill are that it provides a substantial increase in salaries, particularly to the technical employees of the Patent Office; it provides for an increased personnel, and authorizes an increase in fees sufficient to cover the increased expenditures. Due to the low salary scale, the Patent Office has lost a large percentage of its more experienced examiners and workers with technical experience. During the last sixteen months there has been a turnover involving one-fourth of the total force of 437 examiners. As pointed out by Representative Vestal of Indiana, one of the active supporters of the measure, this has caused the work to be handled much more slowly, until the work of the office is 60,000 applications behind. It also was pointed out that the work in the Patent Office is increasing by leaps and bounds. During the calendar year 1919 the number of patent applications totaled more than 76,000—exceeding by 19,000 the number of applications filed in 1918. The 1918 total was exceeded by 24,000 applications in 1920, and 1921 exceeded 1918 by 30,000 applications. In 1921 there were 87,408 applications for patents, 5,596 applications for designs, and 16,234 applications for trade-marks, making a total of 109,238 applications. This is an increase in work during 4 years of 65 per cent. During those 4 years an increase of 5 per cent in personnel was allowed, but in many instances at a salary scale established in 1854.

Technical societies and other organizations are largely responsible for the pressure which forced the passage of the bill over the protest of House leaders. This support came principally from the National Research Council, American Engineering Council, Manufacturing Chemists Association, American Institute of Electrical Engineers, American Patent Law Association, National Association of Manufacturers, American Society of Civil Engineers, American Society of Mechanical Engineers, National Automobile Chamber of Commerce, Automotive Electrical Association, Electrical Manufacturers Club, American Institute of Mining and Metallurgical Engineers, American Bar Association and the American Chemical Society.

Marvin Appointed Chairman of Tariff Commission

The President has designated Thomas O. Marvin to be chairman of the United States Tariff Commission for the year beginning Jan. 15. He has been a member of the Commission since last March. He succeeds to the chairmanship held until this time by Thomas Walker Page, a Democratic member of the Commission. Mr. Page remains as a member of the body.

At the same time the President designated William S. Culbertson to be vice-chairman of the Commission. It is understood that Mr. Marvin will retire within a few months and that Mr. Culbertson will succeed to the chairmanship. Mr. Culbertson is the member of the Commission who has specialized on chemical matters.

New Sugar Refineries in Operation and Additional Expansion Contemplated

The Coca-Cola Co., Atlanta, Ga., has placed a new sugar refinery in operation in connection with its local plant, for the production of sugar exclusively for company service. The mill is equipped for a daily output of about 200,000 lb., and is of experimental character with view to ascertaining accurately the economies to be effected by individual production, rather than buying the commodity in the market. When success has been demonstrated, it is purposed to establish other such plants to furnish material to the fourteen factories of the company throughout the country.

The new refinery of the American Sugar Refining Co. at Baltimore, Md., is nearing completion and will soon be turned over to the company by the contractors. It is expected that this will take place about March 1, and that production at the plant will be commenced before the close of that month. The initial capacity will approximate 10,000 bbl. a day, or about 3,000,000 lb. Arrangements are now being made by the government for the installation of its department at the plant, to consist of electrical weighing machinery, chemical and other testing apparatus for sampling and revenue work. It is said that the government force to be engaged at the plant will total about seventeen persons, including chemists, inspectors, samplers, electricians and laborers. The equipment to be installed in this department is estimated to cost about $100,000.

Chemical Fellowships in Twenty Institutions Again Awarded by Du Pont Company

E. I. du Pont de Nemours & Co., have authorized the continuance of Du Pont chemical fellowships in twenty colleges and universities throughout the United States for the scholastic year of 1922-23 of the total value of $15,000. The fellowships are for post-graduate work and are placed in the institutions which have well-established post-graduate courses. The recipients are selected by the university authorities, the only condition made by the company being that the awards shall go to graduates who devote the major part of their time to the study of chemistry.

The object of the plan is to promote the study of chemistry and to assist deserving students, who have shown especial aptitude for chemistry, to pursue further work. It differs from the usual plan for industrial fellowships in that the company does not insist on the student carrying out an investigation on subjects in which the company is interested, but leaves him free, under the direction of his instructors, to follow whatever line of investigation seems to him most promising.

The institutions which receive these fellowships are Brown University, California Institute of Technology, University of California, University of Chicago, Columbia University, Cornell University, Delaware University, Harvard University, University of Illinois, Johns Hopkins University, Lafayette College, Massachusetts Institute of Technology, University of Michigan, University of Minnesota, Ohio State University, Princeton University, University of Virginia, University of Washington, University of Wisconsin and Yale University.

Leather Company Bans Alien Employees

Effective Jan. 1, the New Castle Leather Co., Wilmington, Del., has adopted a rule that no aliens will be employed at the plant. Employees who are not citizens or who do not take out citizenship papers at once will be dropped from the force. It is said that several months ago the company posted notices requesting that all aliens engaged at the plant become citizens, but the majority at that time declined. In the present instance, the company's decision has brought an influx of applications at the local District Court.

Steel Mills Set the Pace of Increasing Activities in Various Industries

Glass. The John B. Scohy Glass Co., Sisterville, W. Va., is arranging for the resumption of production at its plant, which has been closed down for more than a year past. Employment will be given to about 150 operatives.

Oil. The Denison Oil & Refining Co., Denison, Tex., is arranging for the immediate operation of its new local refinery, rated at a capacity of about 5,000 bbl. per day. The plant was completed several months ago, but production has been deferred until conditions in the industry warranted.

The Waco Refining Co., East Waco, Tex., will commence production at its oil refinery at once, following alterations and improvements in the plant, recently acquired from other interests. William Sacks heads the company.

The Owens Refining Co., Minerva, Tex., is completing the construction of a refinery on local site, with capacity of about 1,500 bbl. a day, and expects to place the plant in operation before Feb. 1.

Rubber. The Intercontinental Rubber Co. has resumed production at its mill at Torreon, Mex., following a shutdown dating from December, 1920.

Copper. The Anaconda Copper Mining Co., Anaconda, Mont., has fired the furnaces at its Washoe smelting plant, as a preliminary heating-up prior to the resumption of operations. The different properties of the company which will start up at an early date include the Leonard, Badger-State, Mountain View and Mountain Consolidated copper mines.

The Boston & Montana Development Co., Butte, Mont., has increased production at its concentrating plant from 50 to 100 tons a day.

The Davis-Daly Copper Co., Butte, Mont., is considering the early resumption of production at its plant, and will send shipments to the Washoe smelting works of the Anaconda Copper Mining Co. About 80 men are now employed for repairs and other miscellaneous operations.

The Utah Copper Co., Bingham, near Salt Lake City, Utah, is planning for the resumption of operations at its properties early in February. About 4,000 men will be employed.

Zinc. The Butte & Superior Mining Co., Butte, Mont., is arranging for the resumption of operations at its local zinc properties.

The Anaconda Copper Mining Co., Great Falls, Mont., has resumed production at its local zinc electrolytic plant.

Iron and Steel. Following the resumption of production at the plant of the Allegheny Steel Co., Brackenridge, Pa., Jan. 16, employment is being given to about 1,000 men.

The Ohio Steel Foundry Co., Lima, Ohio, has resumed production at its plant, following a shutdown since last November. About 500 men will be employed for the present.

The Youngstown Steel & Tube Co., Youngstown, Ohio, has increased operations at its local plant to include twelve of the seventeen furnaces in this district.

The United States Steel Corp. has resumed full operations at its Aetna-Standard plant at Wheeling, W. Va., making three of the company's mills in this district producing in all departments.

The Illinois Steel Co., Chicago, Ill., is maintaining operations at 11 of the blast furnaces at its works.

The Superior Sheet Steel Co., Canton, Ohio, has advanced to full production at its local plant. Since Dec. 1, the works have been running at from 50 to 75 per cent of normal.

The Crane Iron Co., Catasauqua, Pa., is completing the relining of its local blast furnaces, preparatory to the resumption of operations. No date has as yet been announced for blowing in the units.

Metric System Referendum to Be Considered

Whether or not the Chamber of Commerce of the United States will conduct a metric system referendum will be determined at the meeting of the National Council of the Chamber which will be held in Washington, February 8 and 9. The council is made up of one representative each from 1,400 business organizations.

Hearings Before Finance Committee on Cyanide Presage Its Removal From Free List

Unquestionably the controlling sentiment within the Senate Finance Committee favors a duty on cyanides. It is probable that a rate lower than the 33⅓ per cent duty requested will be prescribed in the bill which will be reported to the Senate next month. It may be predicted, however, with considerable certainty that cyanides will be removed from the free list.

The principal point made before the committee was that the gold-mining industry is in no position to add to the expense of producing its fixed-value product. It was shown that, in the case of the Homestake Mining Co. alone, the proposed duty would add $25,000 to its annual cost of cyanide.

Senator Smoot of Utah called attention to the fact that only 0.2 lb. of cyanide is used in treating a ton of ore at the Homestake mine. Since the price of cyanide for the past 8 years never has exceeded 25c. a pound to those using it in quantity, he expressed the opinion that it is not going to add greatly to the cost of production of gold, when the cost of the cyanide used would not exceed 5c. per ton of ore treated.

J. C. Hammitt, of the American Cyanamid Co., expressed the opinion that it would be greatly in the interest of the American consumer to permit a continuance of competition between cyanamide producers. The American Cyanamid Co. entered the American market in 1917 and, according to Mr. Hammitt, is now in a position to offer real competition and to break up the character of exploitation which he alleges existed prior to that time.

Circuit Court of Appeals Denies Petition in Minerals Separation Litigation

The Miami Copper Co. made an argument before the United States Circuit Court of Appeals at Philadelphia on Jan. 18 upon its petition for a writ of mandamus to instruct that the master exclude from the accounting proceedings further testimony as to certain processes which have been in use since those found to have been infringing. It was because of its continued use of these same processes that Minerals Separation, Ltd., sought to have Miami Copper Co. found in contempt of court. The Circuit Court of Appeals in an exceedingly detailed opinion sustained the lower court in its refusal to enjoin the Miami Copper Co. The action upon which the court rendered this lengthy opinion was not appealable, and therefore did not actually require from this court more than its statement of that fact, which it made. The Miami company believed, therefore, that this expression of opinion as to the court's views as to these processes could only have been addressed to the master and litigants, as a means of indicating the manner in which they should proceed. The master, apparently, did not accept this view, and so, in the absence of any guiding precedent, refused the petition that he exclude from the accounting further testimony as to these processes. The Circuit Court of Appeals' dismissal of this petition for a writ of mandamus would apparently simply decide that the reply of the defendants to the prima facie case which, during the past four years, has been set up before the master, shall, on account of the already voluminous record, be answered before the master, rather than by a new bill.

Rate of Duty on Odoriferous Substances Unfit for Use as Perfume

A Treasury decision has just been issued in which it is pointed out that odoriferous substances, shown to be unfit as such to use as perfume but which are used as bases in the manufacture of perfume, take an import duty of 20 per cent ad valorem rather than a duty of 60 per cent ad valorem, which applies to perfumery.

Two New Technical Publications

In response to demands from two of its fields, the McGraw-Hill Co., Inc., began, on Jan. 15, the publication of two new papers, *Bus Transportation* and *Electrical Review and Industrial Engineer.* The former will be published in New York and the latter in Chicago.

Senate Approves Resolution Calling for Detailed Alien Property Report

Since a considerable part of the property which came within the purview of the Alien Property Custodian was in the form of chemical patents and holdings in chemical companies, it is expected that the statement called for from that officer by Senator King's recently approved resolution will be of interest to those engaged in chemical industries.

The resolution calls for detailed information as to the names and compensation of all attorneys appointed or employed by the Alien Property Custodian, and of all attorneys, directors, managers and other agents appointed by the Custodian to administer property under his control. It also calls for the names and compensation of all attorneys of corporations, agents or individuals who have been acting as administrators for the Custodian; names of all attorneys who have represented claimants to property under the Custodian's control; names of all attorneys who have represented claimants to whom property has been returned under Section 9 of the trading with the enemy act, and the compensation allowed each out of the trust funds subject to such claims.

In addition the Alien Property Custodian is required by the resolution to furnish a statement and a description of all property which he has sold, together with the names of the purchasers, and the amount involved in the transaction. A statement of all property seized or demanded since the passage of the peace resolution also is requested.

Industrial Applications of Colloidal Chemistry Subject at Connecticut Section A.C.S.

A. W. Thomas, of the Division of Food Chemistry at Columbia University, addressed the January meeting of the Connecticut Valley Section of the A.C.S. in Springfield, Mass. Choosing as his subject "Rationalization of Colloidal Chemistry," Dr. Thomas spoke of some of the new work that is being done in connection with colloidal solutions, mentioning particularly the peptizing effect of ferric chloride and of hydrogen sulphide respectively in the case of colloidal solutions of ferric hydrate and arsenious sulphide. He also described the preparation of collodion membranes of various degrees of permeability and showed that this means of classifying colloids was unreliable unless a complete description of the method of preparing the dialyzing membrane was available. He spoke of the necessity of simplifying the study of colloid chemistry in order that its phenomena might be better understood and become available for use in the industry. In this connection is the instance of a number of reactions that are truly chemical in their nature, although they have been considered by previous workers to be manifestations of adsorption. Of special value to the industry in this connection is the bleaching of sirup solutions by means of bone black. This has been shown recently to be a case of chemical combinations between compounds in bone black and the colored bodies in the sirup and not a case of adsorption.

Engineering Society of Buffalo, N. Y., Established in Club Quarters

The establishment of permanent club quarters in the Iroquois Hotel has greatly stimulated the activities of the Engineering Society of Buffalo. A series of luncheon meetings has been organized, at each of which it is planned to have an address by some local engineer.

At the regular meeting of the society on Jan. 10, E. B. Neil of the Pierce-Arrow Co. spoke on "Progress in Worm-Gear Designing" and Captain George H. Norton of the Buffalo City Planning Commission outlined the activities of the commission in civic improvement.

R. H. McKee, professor of chemical engineering at Columbia University, will address the meeting on Feb. 14 on the subject "Gasoline From Oil Shale."

Evening Course in Metallography

An evening course in metallography, comprising fifteen lectures and fifteen 2-hour laboratory exercises, will be given at the Brooklyn Polytechnic Institute, commencing Feb. 3. The class will be limited to thirty men.

Technical Societies of Detroit Combine Interests in Newly Formed Association

After several years of thought and discussion along similar lines, the movement for the affiliation of the architectural, engineering and other technical societies of Detroit was taken up seriously in June, 1921, by the organization of a temporary council composed of two delegates from each of the several societies interested. The affiliation has become an accomplished fact, taking effect Jan. 1, 1922, by the ratification of the proposed constitution and bylaws, acceptance of membership and election of councillors by the following twelve societies: Detroit Section, American Society of Civil Engineers; Detroit Chapter, American Association of Engineers; Michigan Chapter, American Society of Heating and Ventilating Engineers; Detroit Post, Society of American Military Engineers; Detroit Section, American Society of Mechanical Engineers; Detroit-Ann Arbor Section, American Institute of Electrical Engineers; American Institute of Chemical Engineers; Detroit Engineering Society; American Chemical Society and Detroit Chemists; Michigan Chapter, American Institute of Architects; Detroit Section, Michigan Society of Architects; Detroit Chapter, American Society for Steel Treating.

The permanent council met and organized Dec. 13, 1921, and elected officers for 1922 as follows: Chairman, P. W. Keating; vice-chairman, A. A. Meyer; secretary-treasurer, Walter R. Meier.

The Associated Technical Societies of Detroit will provide one meeting each month which will be under the management of one of the member societies. This member society will provide the speaker on a broad subject of interest to the members of all the technical societies.

Prize Offered by French Society for Gasoline Substitute

Vice-Consul Davis B. Lewis, of Bordeaux, announces in the Jan. 2, 1922, issue of *Commerce Reports*, the organization of a competition with the object of discovering a practical and economical motor fuel with alcohol as the basis of its composition.

At the recent annual meeting of the Agricultural Society at Beziers, in the neighboring Department of Herault, prizes totaling 200,000 fr. were placed at the disposition of the committee, of which amount 100,000 fr. will be awarded to the competitor whose product gives the best results. The competition will be open from January to March, 1922, and the points to be covered will embrace comparative facility of production of the various substances used; increase or decrease of average power obtained compared with petroleum and gasoline; the possibility of blending the proposed product with gasoline for use in motor engines; the percentage of alcohol and other substances of French origin that are used; average horsepower cost per hour; and the originality of the process.

Complete details of the competition may be obtained from the general secretary of the Committee of Organization, 11 Rue d'Assas, Beziers, Herault, France.

Civil Service Examinations

The Civil Service Commission announces open competitive examinations for the following positions. Vacancies exist in the Chemical Warfare Service, Edgewood Arsenal, Edgewood, Md.

Chemical technologist, $3,600 to $5,000 a year. Associate chemical technologist, $2,500 to $3,600 a year. Assistant chemical technologist, $1,800 to $2,500 a year.

Applications will be received on Form 2118 until Feb. 14, 1922.

Announcement is also made of competitive examinations on Feb. 8, 9 and 10 and March 22, 23 and 24, 1922, for assistant examiner, Patent Office. Applications should be filed at once on Form 1312.

Washington Chemical Society Elects

The Chemical Society of Washington, D. C., has elected officers for 1922 as follows: R. C. Wells, Geological Survey, president; J. B. Reed, Bureau of Chemistry, secretary; H. W. Houghton, Hygienic Laboratory, treasurer.

Cotton Linters for Paper T.A.P.P.I. Subject

The January meeting of the Connecticut Valley Section of T.A.P.P.I. was addressed by S. E. Seaman of the Stamsocott Co. on the subject of cotton linters. Mr. Seaman described in detail the operation of a modern plant producing paper stock from linters.

New Chemistry Building at University of Missouri

The University of Missouri, Columbia, Mo., has received an appropriation of $125,000, to be used for the construction of a new two-story chemistry building.

Obituary

JEAN DUBOIS, business manager of the Roessler & Hasslacher Chemical Co., Perth Amboy, N. J., died suddenly at his residence in that city, Jan. 12, following a lingering illness of nearly a year. He was born at Le Locle, Switzerland, on Nov. 24, 1869, and spent his early years in that country. Following a residence of 8 years in South Africa, he came to the United States and engaged in the phosphate business in Florida. Later, he returned to France to superintend the construction of a large chemical plant. In 1911 he again came to the United States and became connected with the Roessler & Hasslacher company, with which he remained until his death. He was a member of the Atlantic Waterways Association and other organizations, and president of the American Terminal and Waterways Association. His wife, a son and daughter, and both parents, survive him.

THOMAS E. DWYER, president and general manager of the Lead Lined Iron Pipe Co., Wakefield, Mass., died Dec. 26, 1921.

JOHN C. PENNIE, of New York City, died on Dec. 23, 1921. By his death the legal profession lost one of its ablest and best known members. Mr. Pennie had not been in good health since the summer of 1921, when he returned from Paris after service of 6 months as a member of the American Commission to Negotiate Peace. However, he was active in the work of his profession up to a few weeks before his death.

Mr. Pennie was born on Aug. 29, 1858, and was graduated from the Albany High School in 1874. He entered Union College at Schenectady and was graduated in June, 1877, with degrees of Civil Engineer and Bachelor of Arts. Then he attended the Albany Law School and received the degree of Bachelor of Law. In the summer of 1878 he went to Europe and pursued his study at the Universities of Breslau and Göttingen. On his return to this country he was admitted to the bar of the State of New York but decided to devote himself to the patent profession and went at once to Washington, D. C., where he entered the Patent Office as an assistant examiner in January, 1881. He remained in the Patent Office until Dec. 3, 1883, serving as assistant examiner of applications relating to metallurgy and later as assistant and acting examiner of interferences. He resigned from the Patent Office in December, 1883, and entered upon the practice of patent law in partnership with John A. Goldsborough, who had been a primary examiner in the Patent Office, and this partnership was continued until the death of Mr. Goldsborough. In 1904, Mr. Pennie moved to New York and continued his practice there in association with D-Cady Herrick and Judge James J. Farren of Albany. During recent years he was the senior partner of the firm of Pennie, Davis, Marvin & Edmonds.

The high position which Mr. Pennie had attained among the members of the bar specializing in patent law led to his selection as the adviser of the American Peace Commission on patent matters, and he spent the first 6 months of 1919 in Paris advising with the representatives of other countries on the provisions of the peace treaty relating to patents. In appreciation of his work as a member of the commission, King Albert of Belgium commissioned him a Commander of the Order of the Crown. After Mr. Pennie's return to the United States a representative of the King presented to him a medal and certificate of his appointment.

Throughout his professional life Mr. Pennie made a host of friends, all of whom held him in highest esteem for his estimable qualities of heart and mind. His strong characteristics were a broad catholicity of spirit, a genial kindliness toward all men, and a sterling integrity, coupled with a broad faith in and a comprehensive charity for his fellow men. He was a man of rare mental attainments, remarkably sound judgment, and an indefatigable worker in the many fields into which he directed his wonderfully fertile intellect. Even in the busiest intervals of his most exacting profession, he was ever ready to give of his time, knowledge and experience to help anyone less fortunately situated, either professionally or socially.

Personal

FRED P. BAKER, for the past year and a half assistant director of the Boston station of the School of Chemical Engineering Practice of the Massachusetts Institute of Technology, has resigned to accept a position as chemical engineer with the Procter & Gamble Co., Cincinnati, Ohio.

Dr. FRANK R. ELDRED, for 20 years director of the scientific division of Eli Lilly & Co., of Indianapolis, has resigned to engage in consulting work under the firm name of Eldred & Aitkinson. Mr. Aitkinson was formerly chief chemist of the American Hominy Co.

F. M. FEIKER, who went to Washington 8 months ago as assistant to Secretary of Commerce Hoover, and on leave of absence from the McGraw-Hill Co., is now back in his old position as editorial director. He has not, however, completely severed his relations with the Secretary or the department, but has been appointed a special agent of the Bureau of Foreign and Domestic Commerce, to continue in a consulting capacity the work he has been rendering. Under the direction of Mr. Feiker and Dr. Julius Klein, Director of the Bureau of Foreign and Domestic Commerce, the industrial and business contracts of that bureau have been enlarged, business relations with trade association committees have been established and the so-called Commodity Divisions of the bureau created. During Mr. Feiker's stay with the department, *Commerce Reports*, the government's official foreign trade paper, has been changed from a daily to a weekly publication and the monthly "Survey of Current Business" was brought into existence. Mr. Feiker's services extended to the Bureau of Standards, the Bureau of the Census and other parts of the department. He served as editorial adviser on the department's board of editors.

LLOYD A. HALL has severed his connection as manager of Vodin, Inc., to establish a business on his own account under the name of the Chicago Chemical Products Co., Chicago, Ill.

ABEL HANSEN, Perth Amboy, N. J., head of the Fords Porcelain Works of that city, has been re-elected president of the Fords National Bank, Fords, near Perth Amboy.

GEORGE A. MACINTOCH, secretary of the Butterworth-Judson Corporation, New York, has been elected a director of the company to succeed M. F. Chase.

CHARLES A. MAY, head of the Maddock Lamberton Works, Trenton, N. J., has been elected a director of the local Mechanics National Bank.

WILLIAM D. MAINWARING, for the past 11 years connected with the Detroit plant of the Railway Steel Spring Co. as chemist and metallurgical engineer, has opened a consulting business at 866 Rockefeller Bldg., Cleveland, Ohio, as a production engineer. Mr. Mainwaring was formerly connected with the open-hearth department of the Pencoyd plant of the American Bridge Co., during the installation of the continuous process of the manufacture of steel.

E. J. VOSS, of the Graham Brothers Soap Co., Chicago, Ill., has been elected president of the local Perfumery, Soap and Extract Association.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

When Does a Currency Collapse?

How much can a currency depreciate before it becomes worthless? To what low level can the mark sink before Germany becomes bankrupt? These questions and the circumstances from which they have arisen have caused us to revise many of our fundamental notions of political economy and national finance.

Take, for example, the Polish mark, which has a nominal gold value of 23.82 cents in our money, and is now worth but 0.03$\frac{2}{3}$ of a cent. This is a depreciation of 99.9 per cent from par. An even more striking case is that of the Russian ruble, formerly worth 51.45 cents, but with a present value so small that it is no longer handled in the old denominations. Notes of 50,000 and 100,000 rubles are in common use.

The Austrian crown, with a nominal gold equivalent of about 20 cents, can be bought for 0.03$\frac{3}{5}$ cent, and the Hungarian crown of the same par value is worth 0.12$\frac{2}{5}$ cents. That such depreciation is not limited to the nations of central and western Europe is attested by the fact that the escudo of Portugal can be purchased at a discount of 93.5 per cent and the Chilean peso at a discount of 71.8 per cent. It is natural that the question should be asked: How long will a people cling to a currency which is tottering on the very verge of extinction?

One phase of the situation which is not always appreciated is the very great effect caused by even the slightest fluctuation in the values of these depreciated units. When the mark, for example, fell from 1$\frac{1}{2}$ cents in June to about $\frac{1}{3}$ of a cent in December, 1921, there must necessarily have been a tremendous reduction in its purchasing power. Since Germany is importing much of her foodstuffs and raw materials and paying for them at high rates of exchange, commodity prices (except in cases of government subsidy) have risen with the decline in the value of the mark. Wage advances, on the other hand, are comparatively slow, and in the meantime strikes and other evidences of internal industrial disorganization are a natural consequence. The recent report of the U. S. Tariff Commission includes some pertinent comment on the relation between wages and prices:

> A comparison of wages in the United States, England, France and Germany shows that they are less adjusted to a gold basis than are prices. In May, 1921, the standard wage in Germany for factory workers was, roughly, 10 cents per hour in gold as compared with 20 cents to 25 cents in France, 30 to 40 cents in England, and 50 to 75 cents in the United States.

There is a discrepancy of slightly more than 2 to 1 between the internal purchasing power of the mark and its gold value in foreign exchange, according to the commission. This is obviously to the very great advantage of the German exporter who sells in dollars but pays for his labor and materials with marks.

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	143.50
Last week	143.75
January, 1921	181
January, 1920	242
April, 1918	286

This index number, which is based on the wholesale prices in the New York market for a group of twenty-five representative chemicals and related commodities, continued its decline during the past week. Slightly lower prices for caustic soda, formaldehyde, salt cake and citric acid were principally responsible for the change in this week's index number.

RATES OF EXCHANGE OF SOME OF THE PRINCIPAL FOREIGN CURRENCIES AT NEW YORK

Par of Exchange	Foreign Currencies	Federal Reserve Exchange Rates Certified Jan. 18, 1922	Per Cent Depreciation from Par
Cents		*Cents*	
486.65	British pound	422.35	13.21
19.3	French franc	8.15	57.71
23.82	German mark	0.5147	97.8
19.3	Belgian franc	7.80	59.6
23.82	Polish mark	0.0344	99.9
19.3	Greek drachma	4.37	77.5
19.3	Italian lire	4.35	77.6
19.3	Spanish peseta	14.96	22.5
19.3	Swiss franc	19.42	.....
20.26	Austrian crown	0.0316	99.9
20.26	Czechoslovakian crown	1.6803	91.7
20.26	Hungarian crown	0.1244	99.3
26.8	Swedish krona	24.88	7.5
40.2	Netherlands florin	36.71	8.7
108.0	Portuguese escudo	7.42	93.5
51.45	Russian ruble	0.1125	99.7
32.44	Brazilian milreis	12.51	61.5
36 50	Chi ean peso	9.75	71 8
100	Canadian dollar	94.75	5.3

Brief Market Notes About Chemicals and Related Commodities

Naval Stores. The estimate of the Department of Agriculture for the production of gum turpentine during the 1921-22 season is 427,000 casks of 50 gal. each. The estimate for gum rosin is 1,320,000 bbl. of 280 lb. The corresponding production during the 1920-21 season was 488,690 casks and 1,577,390 bbl.

Paradichlorbenzene. A bulletin recently issued by the Bureau of Entomology of the Department of Agriculture describes the use of paradichlorbenzene as a means of preventing or lessening the ravages caused by the peach borer. Experiments begun in 1915 and carried on largely under the direction of E. B. Blakeslee and A. L. Quaintance of the bureau showed "paradichlor" to be particularly effective in preventing the peach borer from attacking and seriously injuring the trees. It is applied in the fall of the year around the base of the tree and about 2 in. from the trunk. One pound is said to be sufficient for 16 trees.

A large-scale demand for paradichlorbenzene would be welcomed by chemical manufacturers.

Chemical Glassware. Exports of chemical glassware for the 11 months ended Nov. 30, 1921, were valued at $215,294. During the month of November the exports, which amounted to $12,692, were shipped to twenty-one different countries.

In amount this may seem but a trivial item, but it is extremely significant that the United States, formerly entirely dependent on a foreign source of supply for all chemical and scientific glassware, has now developed an industry which is capable of competing with the German and Austrian manufacturers not only in the United States but in many of the principal foreign markets of the world.

Wholesale Prices in December

Reference was made in these columns last week to the price indexes of the Bureau of Labor Statistics, the most recent figures being those for the month of November. On Jan. 19 the bureau announced that the index number for all commodities stood at 149 for December, the same as in the previous month. Farm products and foods again showed a downward tendency. Chemicals and drugs fell off slightly, the index number changing from 162 to 161. Metals remained constant at 119.

The New York Market

NEW YORK, Jan. 23, 1922.

The consuming industries have shown some interest in the chemical market during the past week, although the actual volume of business has been rather small. Large-lot buying was exceptional and most of the consumers were contracting only for actual requirements. Prices along the entire list have remained quite steady. The interest in prussiate of soda has continued and high prices have been maintained, with very little offered either for spot or contract purchases. Prussiate of potash, however, has been in increasing demand, both for the red and yellow. Orders have been in the market for the former as high as 32c. per lb., but holders have advanced prices to 33@34c. per lb. The yellow has sold at 25c. per lb., ex-store. The market for arsenic continued very strong. Leading factors are of the opinion that large quantities will be extremely difficult to locate in the very near future, because of the scant importations. Domestic producers are not anxious to supply the trade at present prices, but are waiting for a substantial rise in the market. Their quotations range from 7@7½c. per lb., while odd resale lots sold as high as 8c. per lb. on the spot.

Producers of chlorate of soda have reduced prices to 7c. per lb. Imported material can be bought as low as 6¼c. per lb. Makers of chlorate of potash are still quoting 12c. per lb. on the powdered, but it is commonly known that shading on firm business is being done by leading dealers. Importers are generally holding their material at fairly high prices to make purchases under 6@6¼c. per lb. on spot. Shipment material from abroad is offered at 5¾c. per lb. Manufacturers of barium chloride quote $50 per ton for quantity shipments. Importers are having difficulty in competing with the domestic quotations at present. Additional sales of solid caustic soda for export were reported at $3.60 per 100 lb. Small-lot sales have gone through at 3¾c. per lb. Producers quote the market for contract at $2.60 per 100 lb., basis 60 per cent, f.o.b. works. Small-lot trading in light soda ash, single bags, was reported at $1.90@$1.95 per 100 lb. on spot. Dealers stated that carload quantities have been moved at $1.75 per 100 lb. Offerings were rather scarce and producers stated that contracts were being booked at the works at $1.35 per 100 lb., basis 48 per cent. Makers of bichromate of soda quote 7½@8c. per lb., with only a moderate demand from consumers. Bicarbonate of soda is quoted at 2c. per lb. f.o.b. works for barrels and 2¼c. for kegs. Offerings on spot in carlots have been heard at $2.15 per 100 lb., and smaller quantities at $2.30. The buying movement is rather quiet at present, although a steady call on contract shipments is reported. The tartaric acid market has shown signs of weakness and prices at the close were decidedly lower for imported material. The demand has not been active and considerable competition has developed among holders. Final quotations were 24@25c. per lb. for crystals and 25@26c. per lb. for the powdered. Domestic prices remained quotably unchanged.

COAL-TAR PRODUCTS

The coal-tar products market has undergone some revision in prices since the beginning of the year. Evidence of keen competition is reflected in the course of many prices. Consumers are not buying freely, because the market is flexible enough to suggest that future prices may be more attractive. Benzene continues to command considerable attention and refiners are holding prices firm at the recent advance. The c.p. grade is quoted at 29@35c. per gal. in tank cars and drums. Naphthalene is another item receiving attention and prices in refiners' hands are held steady at 7½@8½c. per lb. for the flake. Inquiries are resulting in placing a moderate amount of business for the coming season. A steady absorption of spot supplies of phenol has placed this commodity in a stronger position. A price of 12c. per lb. was considered a very attractive figure for the U.S.P., while the range extended all the way up to 16c. A fair inquiry for domestic consumption was recorded.

The St. Louis Market

ST. LOUIS, Mo., Jan. 20, 1921.

There has been a noticeable improvement in the chemical line since Jan. 1 in this section, although reports from other quarters do not disclose any real change. It is not expected that there will be any sudden expansion in business, but that there will be a steady increase from week to week.

ALKALIS

Caustic soda remains firm at the same price as last week, $3.40 per 100 lb. for 76 per cent solid in drums in carlots at point of production, single drums at $4.25 per 100 lb. f.o.b. St. Louis. The 76 per cent flake is quoted at $4 per 100 lb. at point of production in carlots, while single drums are held at $4.87½ f.o.b. St. Louis. Contracts are being executed at this price with protection against decline. Bicarbonate of soda is moving slowly at $2.90 per 100 lb. in single barrels, $2.65 per 100 lb. in 10-bbl. lots. Salsoda at buyer's command, at $2 per 100 lb. in single barrels.

GENERAL AND SPECIAL CHEMICALS

Acid citric fails to show any increase. Gallic and pyrogallic acids are in better demand. Phosphoric acid is moving more freely. While the demand for tartaric acid at the close of last year was practically nil, the demand since the beginning of this year has been very gratifying. Ammonium sulphate is moving fairly well, but the demand is not as large as expected. A larger volume of business is being passed on barium sulphate; furthermore, the inquiries for blanc fixe are increasing. Cream of tartar continues to move in a routine way. The market on glycerine is very firm at 16c. in drums, and a further raise of ½c. is expected. Demand is strong. Sulphur is moving slowly, and the price is getting weaker.

VEGETABLE OILS AND NAVAL STORES

Turpentine reached the highest price for some time when it sold for 97c. in single barrels last week. It can now be obtained for 93c. The demand is strong. Linseed oil is keeping step with the flaxseed market, and is now being held at 75c., basis raw oil in cooperage. Contracts for future delivery after May 1 are being taken at the prevailing price of 75c. Castor oil is entirely in the producers' hands and is being held firmly at 13c. per lb.

PAINT MATERIALS

Lithopone is being held at 6c. for carlots and 6½c. in less than carlots by the producers in this locality. Only one of the three plants in this district is in operation. Imported goods are a disturbing factor. Barytes is still holding at $23 in ton lots. This has been shaded on carlot inquiries. Demand is only fair. Whiting of all grades and all prices is being offered in this market at $11 per ton in carlots for air floated, with as high as $15 for water ground and water floated.

The Iron and Steel Market

PITTSBURGH, Jan. 20, 1922.

Demand for steel products in the past week has been of decidedly moderate proportions. The volume of business is perhaps heavier now than in the first two weeks of January, but it can scarcely be regarded as showing as much improvement as would be expected, now that the holidays and the annual inventory date are left behind. There is not a reversion to the conditions of October and November, when buying was sufficient to support steel production at the rate of fully 23,000,000 tons a year. This was not a high rate, generally speaking, but it was the highest rate shown since February. The average rate of production during December was 20,000,000 tons a year, the rate being above this at the beginning of the month and lower at the close. It is doubtful whether the rate now is as high as 20,000,000 tons. This, by the way, is about 38 per cent of the entire capacity in existence and somewhat under 50 per cent of the capacity of the strongest companies, those with the best facilities for economical production.

The demand for steel that has come out in the past week would scarcely be a safe criterion as to what is to be expected in the next few weeks or months, the period since the

first of the year being too short for guidance, but there is some contributory evidence in the attitude of the mills. This attitude has been very aggressive. All orders of any size are strenuously contested for by every available means, including price concessions.

Regular prices are no lower in the case of any important finished steel product, there having indeed been no change in this respect for a month, or since the formal reduction in wire prices by the leading interest. The change in the week is simply that prices below the regular level are being made on somewhat smaller tonnages, and thus the average of the entire tonnage sold is slightly reduced. The majority of orders placed are at full prices. This can easily be the case without its meaning much as to market stability, for the reason that the majority of buyers are ordering in single carloads. Regular prices are as follows: Bars, shapes and plates, 1.50c.; hoops, 2c.; plain wire, 2.25c.; wire nails, $2.50; standard steel pipe, 71 per cent basing discount; blue annealed sheets, 2.25c.; black sheets, 3c.; galvanized sheets, 4c.; tin plate, $4.75.

Manufactured steel products continue to show a general declining tendency, but in this they are merely following the rolled steel materials from which they are made. Generally speaking, the manufactured products have been rather tardy in their response. In most cases these materials are at higher percentages above their pre-war levels than are rolled steel products. The base price of chain, on 1-in. proof coil, has been reduced from 5.90c. to 5.50c., and differentials have been so revised that greater reductions have been made on some descriptions of chain, such as BB. Railroad spikes are down from 2.25c. to 2.15c. or 2.10c., depending on size of order, and small spikes, boat and barge spikes are down to 2.35c. or 2.40c. even on quite moderate sized orders. Rivets remain at 2.25c. for structural and 2.35c. for boiler, but are far from firm at these figures. Cold-finished steel bars are quite irregular and present no well-defined market price.

Pig Iron and Coke

Pig iron continues decidedly quiet and prices are unchanged, perhaps partly because there has been no inquiry of sufficient importance to develop competition. The market is quotable at $19.50 for bessemer, $18.25 for basic and $19.50 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

These prices are all below the current cost of production, basing cost on present market prices for Connellsville coke and last season's prices on Lake Superior ore. Basic iron is particularly low. Its decline seems to have been due to the selling of iron by steel works, not necessarily because of steel works having a lower cost than merchant furnaces, but in part at least because the steel works had unfortunately accumulated the iron and it is more economical for them to make fresh molten iron than to melt the stock iron. Some of the steel works, however, have byproduct coke ovens and a lower production cost, other things being equal, than merchant furnaces that buy their coke.

Connellsville coke for spot shipment, reported stiffer a week ago, has softened again, as odd lots can be picked up at $2.75. Probably not much could be found at $2.75, but there is at least as much as the market is disposed to absorb. The blast furnaces rarely buy any spot coke nowadays, since deliveries on contract are ample, and the buying is restricted to the miscellaneous consumers, brick yards, bakeries, etc., whose purchases are always relatively small. Contract furnace coke shows no developments, the business for the current quarter being all done, with the last contract reported at $3.10, the lowest price done in the contract movement.

Spot foundry coke is easier, and is quotable at $3.75@$4.25, against a range of $3.75@$4.50 formerly quoted. The $4.50 coke is practically out of the market. There have been offerings at $3.50 in the past week, but they scarcely justify inclusion of the price in the market range. One set of offerings is of a coke that is not selected according to standard practice, while other offerings were by a producing interest whose ovens are idle, the object apparently being to accumulate a tonnage that could be offered in a lump to producers in hopes of getting a special price.

General Chemicals

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	$1.00 — $1.05
Alpha-naphthol, refined	lb.	1.15 — 1.20
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.17 — .18
Aniline salts	lb.	.25 — .26
Anthracene, 80% n drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P	lb.	1.35 — 1.45
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.75 — .85
Benzoic acid, U.S.P	lb.	.60 — .65
Benzoate of soda, U.S.P	lb.	.52 — .55
Benzene, pure, water-white, in drums (100 gal.)	gal.	.29 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.27 — .32
Benzyl chloride, 95-97%, refined	lb.	.27 — .29
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.70 — .75
Beta-naphthol, tech	lb.	.30 — .32
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .17
Ortho-cresol, in drums (100 lb.)	lb.	.24 — .26
Cresylic acid, 97–99%, straw color, in drums	gal.	.65 — .70
Cresylic acid, 95-97%, dark, in drums	gal.	.60 — .65
Cresylic acid, 50%, first quality, drums	gal.	.45 — .50
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.90 — 1.05
Dimethylaniline	lb.	.40 — .45
Dinitrobenzene	lb.	.21 — .25
Dinitroclorbenzene	lb.	.25 — .27
Dinitronaphthalene	lb.	.32 — .35
Dinitrophenol	lb.	.38 — .40
Dinitrotoluene	lb.	.25 — .30
Dip oil, 25%, car lots, in drums	gal.	.31 — .35
Dipnenylamine	lb.	.60 — .70
H-acid	lb.	.95 — 1.05
Meta-phenylenediamine	lb.	1.05 — 1.10
Monochlorbenzene	lb.	.10 — .12
Monoethylaniline	lb.	1.30 — 1.40
Naphthalene crushed, in bbls	lb.	.07 — .08
Naphthalene, flake	lb.	.07 — .08
Naphthalene, balls	lb.	.08 — .09
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.15 — .17½
Ortho-amidophenol	lb.	2.85 — 2.90
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.15 — .20
Ortho-toluidine	lb.	.20 — .25
Para-amidophenol, base	lb.	1 25 — 1.30
Para-amidophenol, HCl	lb.	1 45 — 1.50
Para-dichlorbenzene	lb.	17 — 18
Paranitroaniline	lb.	77 — .80
Para-nitrotoluene	lb.	70 — .75
Para-phenylenediamine	lb.	1 60 — 1.65
Para-toluidine	lb.	1 10 — 1.15
Phthalic anhydride	lb.	37 — .40
Phenol, U. S. P., drums	lb.	.12 — .16
Pyridine	gal.	1.75 — 2.75
Resorcinol, technical	lb.	1.40 — 1 50
Resorcinol, pure	lb.	2 00 — 2 25
Salicylic acid, tech., in bbls	lb.	.20 — 21
Salicylic acid, U. S. P	lb.	23 — .24
Salol	lb.	.75 — 77
Solvent naphtha, water-white, in drums, 100 gal	gal.	.25 — .28
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.14 — .16
Sulphanilic acid, crude	lb.	.26 — .28
Tolidine	lb.	1 20 — 1 30
Toluidine, mixed	lb.	.32 — .38
Toluene, in tank cars	gal.	.25 — 28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal	lb.	.40 — 45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — ....
Xylene, commercial, in drums, 100 gal	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — ....

Waxes

Prices based on original packages in large quantities.

Bayberry Wax	lb.	$0.20 — $0.21
Beeswax, refined, dark	lb.	.24 — .25
Beeswax, refined, light	lb.	.28 — .30
Beeswax, white pure	lb.	.34 — .38
Candellila wax	lb.	.23 — .24
Carnauba, No. 1	lb.	.45 — .46
Carnauba, No. 2, North Country	lb.	.22 — .22½
Carnauba, No. 3, North Country	lb.	.13½ — .14
Japan	lb.	.19 — .20
Montan, crude	lb.	.04½ — .05
Paraffine waxes, crude match wax (white) 105-110 m.p	lb.	.04¼ — .04¾
Paraffine waxes, crude, scale 124-126 m.p	lb.	.03¼ —
Paraffine waxes, refined, 118-120 m.p	lb.	.03 — .03½
Paraffine waxes, refined, 125 m.p	lb.	.03½ — .03¾
Paraffine waxes, refined, 128-130 m.p	lb.	.04 — .04¼
Paraffine waxes, refined, 133-135 m.p	lb.	.04½ — .05
Paraffine waxes, refined, 135-137 m.p	lb.	.05½ — .05½
Stearic acid, single pressed	lb.	.09¼ — ...
Stearic acid, double pressed	lb.	.09½ — ...
Stearic acid, triple pressed	lb.	.10½ — .10¾

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES — The Southern Pacific Railroad Co., 65 Market St., San Francisco, has completed plans for the construction of a new creosoting plant at Wilmington, Los Angeles Harbor, to consist of five 1-story buildings, estimated to cost about $150,000 with equipment. The erection contract has been let and work will be placed under way at once.

BURBANK — The American Aluminum Products Co., Los Angeles, care of Richard D. King, 519 Van Nuys Bldg., architect, has taken bids for the erection of its proposed new plant at Burbank, to consist of a group of 7 buildings, estimated to cost in excess of $75,000.

Connecticut

NEW LONDON—The Robert Gair Co., 45 Washington St., Brooklyn, manufacturer of paper boxes, containers, etc., is considering the erection of a new plant in Connecticut, on site in the vicinity of its New London works. The company has arranged for a mortgage of $6,000,000 on its properties, to provide for increased working capital and expansion, including the proposed new mill.

NEW HAVEN—Fire in the 4-story factory at 138-44 State St, occupied by a number of industrial concerns, destroyed a portion of the works of the Elm Novelty Mfg. Co., manufacturer of paper boxes, with a loss estimated at about $20,000; C. H. Pulkin, paper goods, with loss of about $15,000, and the plant of the Central Brass Co., with loss of about $8,000.

Florida

MOORE HAVEN—The City Council is planning for the installation of a new filtration plant at the municipal waterworks.

Georgia

CAMILLA — Fire recently destroyed a portion of the plant of the Camilla Cotton Oil & Fertilizer Co., with loss estimated at about $20,000.

Iowa

DUBUQUE—The Globe Portland Cement Co., 416 McKnight Bldg., Minneapolis, Minn., will break ground about March 15 for the erection of its proposed new cement plant at Dubuque, consisting of a number of mill buildings, estimated to cost about $1,500,000. The C. L. Pillsbury Co., 1200 Second Ave., South Minneapolis, Minn., is engineer.

Maryland

BALTIMORE — The American Concrete Tile & Products Co., 305 Gaither Bldg., recently organized with a capital of $250,000, has preliminary plans under way for the erection of a new plant on local site, estimated to cost about $70,000, including machinery. The company will specialize in the manufacture of brick, tile, blocks and kindred products. John E. Springer is president, and John W. Ritter, secretary and treasurer.

BALTIMORE — The Consolidated Gas, Electric Light & Power Co, Lexington Bldg., has filed plans for the construction of a new steel gas holder at its gas-manufacturing plant, 278 ft. in diameter, and 225 ft. high, to cost $860,000. The Bartlett-Hayward Co., Scott and McHenry Sts., has the erection contract.

BALTIMORE — In connection with the enlargement of its oil refinery in the Canton district, now under way, the Standard Oil Co., Pratt and Commerce Sts., purposes to make this plant the second largest works of its kind in the country, with capacity for handling about 56,000 bbl. of crude oil per day, the larger amount of which will be from the Mexican fields of the company. Extensive storage facilities will be provided.

Massachusetts

SPRINGFIELD — The Strathmore Paper Co. has awarded a contract to the Casper Ranger Construction Co., Holyoke, Mass., for the construction of an addition to its plant.

WALTHAM — The Elastoid Fiber Co., Norman and Marshall Sts., is arranging for the early occupancy of its new 1-story plant addition, 72 x 180 ft., now in course of erection, to include a 1-story power house. All miscellaneous contracts have been let. The plant will cost about $35,000.

ASHLAND — Fire, Jan. 10, destroyed a portion of the plant of the Angier Mills, Main St., manufacturers of waterproof papers, with loss estimated at about $200,000. The plant consisted of three main buildings.

MALDEN—Wadsworth, Howland & Co., Inc., 139 Federal St., Boston, manufacturer of paints, etc., has awarded a contract to Coleman Bros., Charlestown, Mass., for the construction of a 4-story addition, 40 x 80 ft., to its plant on Green St., Malden, estimated to cost about $27,000.

Michigan

CLAWSON—The Clawson Brick & Tile Co. has acquired a local site for the construction of a new plant, to be equipped for the manufacture of brick, tile and other burned clay products.

CADILLAC — Construction has been inaugurated on a new 1-story and basement foundry, 87 x 100 ft. on local site, to be owned and occupied by a new company now being organized by R. J. Teetor of the Mitchell Digging Iron Co., Cadillac. It will be equipped for the manufacture of iron, steel and other metal castings, and is estimated to cost in excess of $100,000. Frank D. Chase, Inc., 646 North Michigan Ave., Chicago, Ill., is architect and engineer.

Missouri

CAPE GIRARDEAU — The Cape Girardeau Portland Cement Co. is planning for extensions and improvements in its plant, including the remodeling of certain portions of the works and the installation of new grinding and other machinery. It is purposed to develop an output of about 2,400 bbl. per day. New equipment will be installed at the power plant. The work is estimated to cost about $150,000. Charles L. Harrison is president.

ST. LOUIS—The Obear-Nester Glass Co., 25 North 2nd St., is considering preliminary plans for the construction of a 1-story addition to its glass manufacturing plant at Broadway and Belt Sts., East St. Louis, Ill., estimated to cost approximately $75,000.

MONETT — The Hammond Dehydration Co. has plans under way for the construction of a new 2-story dehydration plant on local site. Hickenlively & Marks, Landers Bldg., Springfield, Mo., are architects.

New Jersey

CROSSWICKS — The General Rendering Co., a subsidiary of Wilson & Co., U. S. Stock Yards, Chicago, Ill., will make a number of alterations and improvements at its local plant, and has temporarily discontinued operations for this purpose. The machinery will be modernized and capacity increased. Wylie E. Brown is manager.

PERTH AMBOY — The Raritan Copper Works, foot of Elm St., a subsidiary of the Anaconda Copper Co., 25 Broadway, New York, is perfecting plans for the manufacture of copper shingles and affiliated products at its plant, and machinery for this purpose will be installed at an early date. It is planned to manufacture, also, copper leaders, gutters, etc.

New York

LONG ISLAND CITY — The Standard Sanitary Mfg. Co., Bessemer Bldg., Pittsburgh, Pa., manufacturer of sanitary ware, has acquired the plant of the Goodyear Tire & Rubber Co., Jackson Ave. and Honeywell St., Long Island City, for an eastern works. It consists of a 6-story building, aggregating about 63,000 sq.ft. of floor space, and was secured for a consideration said to be $500,000. Operations will be inaugurated at an early date.

Oklahoma

OKMULGEE—The Highway Oil Refining Co. is completing plans for the rebuilding of its local gasoline plant, recenty destroyed by fire with loss estimated at about $25,000. W. E. Burke is secretary and manager.

TULSA—The Brite-Lite Polish Co., 411 Robinson Bldg., recently organized, has plans in preparation for the construction of a new local plant, 50 x 75 ft., for the manufacture of polishes. Machinery will be installed for an initial capacity of about 500 bottles per day. S. S. Bassett is vice-president, and P. G. Hefflefinger, secretary and treasurer.

Ohio

TOLEDO — The Electric Glass Co., 505 St. Clair St., has awarded a contract to Otto C. Hoelzer, 706 West Central St., for the erection of a new 2-story plant at 1310 Front St., to be used for the manufacture of glass specialties. Henry Pingen is president and treasurer.

Pennsylvania

PHILADELPHIA — The Boice Folding Box Co., Inc., a new organization, manufacturer of paper folding boxes and containers, is completing plans for the construction of a new plant at Ogden and Hutton Sts. E. L. Rothschild, 1420 Chestnut St., is architect. Wilson Scott Boice, 4020 Spruce St., is president of the company.

POTTSTOWN — The Vulcweld Rubber Co., manufacturer of automobile tires and other rubber products, is having plans prepared for the construction of a new 2-story plant, 60 x 260 ft., on site recently acquired on West High St. A 1-story power house, 40 x 65 ft., will be erected, also. The plant is estimated to cost about $200,000. E. W. Smith heads the company.

PITTSBURGH — The Thermatomic Carbon Co., a new organization, headed by R. H. Uhlinger, 3612 Bates St., is arranging for the erection of a new plant on site selected in Louisiana, for the manufacture of carbon black and affiliated products. A permit has been granted by the Louisiana State Department of Conservation for the new works.

Tennessee

CHATTANOOGA — The Signal Mountain Portland Cement Co., James Bldg., will break ground early in March for the construction of its proposed new plant in the vicinity of Chattanooga. The mill will consist of a number of buildings, and is estimated to cost in excess of $500,000. J. L. Senior is president.

KNOXVILLE — The Knoxville Cement Products Co., manufacturer of cement bricks, tile, blocks and kindred products, is planning for the installation of additional machinery at its plant. The company was organized recently under state laws. C. P. Koehn is president and manager.

CHATTANOOGA — The Ocoee Copper Co., 1135 Volunteer Life Bldg., will take bids early in February for the construction of its proposed new flotation plant at Ducktown, near Chattanooga, on site recently acquired. It will be completely equipped for the treating of copper ores, and is estimated to cost about $200,000. J. I. Carter is president, and L. P. Hope, engineer in charge.

Washington

VANCOUVER—The Pacific States Rubber Co., recently organized by A. M. Elliott, Vancouver, and associates, is arranging for the purchase of a local site for the construction of a large plant for the manufacture of rubber products of various kinds. The initial plant unit will cost about $500,000, and later extensions will bring the investment up to more than $1,000,000. Plans for the plant will be prepared at an early date.

West Virginia

NITRO—The Seydel Mfg. Co., 86 Forrest St., Jersey City, N. J., manufacturer of chemical products, is arranging for the establishment of a large plant on site recently acquired at Nitro, and for which purpose a company of similar name has lately been organized with capital of $1,500,000, effecting a merger between the Seydel company and the Nitro Products Co., manufacturer of like specialties. Operations will be concentrated at the new location and the present plant removed to this point. Herman Seydel heads the company.

New Companies

THE TEXALO OIL CORP., Buffalo, N. Y., has been incorporated with a capital of $300,000, to manufacture oil products. The incorporators are B. Rumsey, J. Argue and B. F. Milsom. The company is represented by Abbott & Abbott, Iroquois Bldg., Buffalo.

THE PHILADELPHIA PORCELAIN CO., Woodlynne, N. J., has been incorporated with a capital of $50,000, to manufacture porcelain ware of various kinds. The incorporators are William T. Allen, William A. Leiser and John Tuthill, Woodlynne.

THE ANDERSON MAGNESIA PRODUCTS CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture magnesia and asbestos goods. James G. Anderson, 47 Harvard St., is president and treasurer; John G. Anderson is secretary.

THE DAWSON BRICK CO., Dawson Springs, Ky., has been incorporated with a capital of $20,000, to manufacture brick and other burned clay products. The incorporators are Lee O. Dixon, Charles F. Cato and I. N. Day, all of Dawson Springs.

THE NATIONAL PRODUCTS CO., 3058 West Harrison St., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are Max Schwartz and Harry Robbins.

THE CARBON FIREBRICK & COAL CO., Carbon, Ind., has been incorporated with a capital of $25,000, to manufacture firebrick and other refractory products. The incorporators are J. L. Sydenstricker; E. L. Strader and Benjamin Simpson, all of Carbon.

THE PHOENIX RUBBER CO., Brockton, Mass., has been incorporated with a capital of $25,000, to manufacture and deal in rubber goods. Charles D. Wener is president; and Charles D. Burnes, 100 Columbia St., Brookline, Mass., treasurer.

THE THOMPSON CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $1,000,000 under Delaware laws, to manufacture chemicals and chemical byproducts. The company is represented by the United States Corporation Co., 65 Cedar St., New York.

THE MERVYN LABORATORIES, Brooklyn, N. Y., has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are S. W. Green, S. Richardson and B. Rafkin. The company is represented by Bertrand Ettinger, 50 Court St., Brooklyn.

THE MARYLAND STEEL CORP., 4th and C Sts., Baltimore, Md., has been incorporated with a capital of $100,000, to manufacture steel, nickel, copper and other metal products. The incorporators are Irving Reynolds, Louis H. Reuter and A. Arthur Jenkins.

THE IMPERIAL POLISH CO., Philadelphia, Pa., has been incorporated with a capital of $10,000, to manufacture polishes and kindred specialties. Henry C. Watt, 618 North 43rd St., Philadelphia, is treasurer.

THE CARBON DIOXIDE PLANT FOOD CO., St. Augustine, Fla., has been incorporated with a capital of $4.500, to manufacture fertilizer specialties. W. B. Guy is president; Bobert Ranson, vice-president and R. D. Crawley, St. Augustine, secretary and treasurer.

THE UNITED RUBBER CORP., Portland, Me., has been incorporated with a capital of 1,000 shares of stock, no par value. to manufacture rubber products of various kinds. Edgar J. Warren is president and treasurer. Doris I. Laffin, Portland, is representative for the company.

THE DRY COLOR CORP., Wilmington, Del., has been incorporated under state laws with capital of $2,050,000 to manufacture colors, chemical products, etc. The company is represented by the United States Corporation Co., Dover, Del.

THE CREAM CITY MIRROR PLATE CO., Milwaukee, Wis., has been incorporated with a capital of $50,000, to manufacture mirrors, glass products, etc. The company will succeed the company of the same name, with local plant, recently dissolved. The incorporators are H. R. Seidel, Edward H. Smith and William Mauthe. The company is represented by Bloodgood, Kemper & Bloodgood, Mitchell Bldg., Milwaukee.

THE MERIDIAN FIBRE CO., Meridian, Miss., has been incorporated with a capital of $35,000, to manufacture fiber products. The incorporators are A. J. Lyon, R. L. Tinsley and Stanton Brown, all of Meridian.

THE R. W. SHEETS PAPER BOX CO., 1008 Mulberry St., Rockford, Ill., has been incorporated with a capital of $100,000, to manufacture paper boxes and kindred products. The incorporators are R. M. Anderson, R. W. and C. A. Sheets.

THE MATE CORP. OF AMERICA, Huntington, L. I., N. Y., has been incorporated with a capital of $350,000, to manufacture chemicals, drugs and affiliated products. The incorporators are T. J. Doran, F. P. J. Crowley and H. Quick. The company is represented by John Boyle, Jr., 570 East 161st St., New York.

THE AMERICAN RADIUM APPLIANCE CO., Morristown, N. J., has been incorporated with a capital of $100,000, to manufacture radium specialties. The incorporators are Ernest B. Rubsamen, Samuel C. Cutler and Francis H. Glazebrook, 171 South St., Morristown.

THE WALLINGFORD STEEL CO., Wallingford, Conn., has been incorporated with a capital of $200,000, to manufacture steel and other metal products. The incoroprators are C. W. Leavenworth, F. A. Wallace and E. B. Cleborne, all of Wallingford.

THE DESOTO OIL AND GAS CO., Jacksonville, Fla., has been incorporated with a capital of $100,000, to manufacture petroleum products. J. E. Johnson, Orange, Tex., is president and manager; P. V. Summers, Jacksonville, vice-president; and Herschel Ehlert, Houston, Tex., secretary and treasurer.

THE MEAKER SPARK PLUG CO., Detroit, Mich., has been incorporated with a capital of $10,000, to manufacture porcelain spark plugs. The incorporators are Ralph H. Meaker, Edward F. Loud and Harry L. Pierson, Jr., 7939 Lafayette Ave., Detroit.

THE STERLO DRUG & CHEMICAL CO., Richmond, S. I., N. Y., has been incorporated with a capital of $50,000, to manufacture chemicals, chemical byproducts, drugs, etc. The incorporators are W. P. and P. F. Tiernan, and J. S. Minogue, Jr. The company is represented by J. H. Tiernan, Cedar Grove Beach, Dongan Hills, S. I.

THE PALMETTO OIL CO., Tulsa, Okla., has been incorporated with a capital of $50,000, to manufacture petroleum products. The incorporators are Stanley D. Campbell, Ray S. Fellows and Albert H. Bell, all of Tulsa.

THE NORTH RIVER BRICK CO., New York, N. Y., has been incorporated with a capital of $50,000, to manufacture bricks. The incorporators are F. Demovitch, M. M. Sherower and F. Raab. The company is represented by Joseph, Demov & Feinstein, 277 Broadway, New York.

THE HOLLAND TILE & GRAVEL CO., Holland, Mich., has been incorporated with a capital of $25,000, to manufacture burned clay drain tile, sewer pipe and cement products. The incorporators are George J. Huntley, W. E. Dunn and H. E. Dunn, all of Holland.

THE MODERN CHEMICAL CO., Wilmington, Del., has been incorporated with a capital of $100,000, under state laws, to manufacture chemicals and chemical byproducts. The incorporators are William B. Clark and Mark R. Yates, Washington, D. C. The company is represented by Charles G. Guyer, 826 Market St., Wilmington.

THE SWITZER-PARKE CO., Houston, Tex., has been incorporated with a capital of $30,000, to manufacture baked enamels, drying paints, etc. The incorporators are Homer E. and S. J. Switzer, Melville B. and W. M. Parke, all of Houston.

THE JOHN H. WALSH CO., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture leather specialties, bookbinders' paste and other kindred products. The incorporators are John H. and F. G. Walsh, and W. A. Smith. The company is represented by Guggenheimer, Curtin, Coyle & Glynn, 233 Broadway, New York.

THE MOCKLAIR CORP., New York, N. Y., has been incorporated with a capital of $100,000, to manufacture fiber products. The incorporators are H. A. Mocklair, H. May and G. E. McArdle. The company is represented by Butcher, Tanner & Foster, 1 Madison Ave., New York.

THE CHEMICAL INK CO., Brooklyn, N. Y., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are J. A. Selas, K. Dyer and W. H. Stieglitz. The company is represented by M. J. Moore, 141 Broadway.

THE DUMONT FERTILIZER CO., INC., Wilmington, Del., has been incorporated with a capital of $500,000, to manufacture fertilizer products. The company is represented by the Corporation Service Co., Wilmington.

THE ENAMEL PRODUCTS CO., INC., Indianapolis, Ind., has been incorporated with a capital of $15,000, to manufacture vitrous enamel products. The incorporators are L. B. Mosiman, B. C. Street and R. C. Street, Indianapolis.

Capital Increases, Etc.

THE SHAFFER OIL & REFINING CO., Oklahoma City, Okla., manufacturer of refined oil products, with office at 208 South La Salle St., Chicago, Ill., has arranged for a bond issue of $1,500,000, for general financing, operations, etc.

THE JOHNSTON CHEMICAL CO., Shepherd, Mich., has filed notice of dissolution under state laws.

THE NEW YORK QUEBRACHO EXTRACT CO., 80 Maiden Lane, New York, N. Y., has filed notice of change of name to the Tanni Corp.

THE CORONA CHEMICAL CO., 16 East 40t St., New York, N. Y., has filed notice of in crease in capital from $25,000 to $500,00

THE KING PHILIP OIL CO., New Bedford, Mass., has filed notice of increase in capita from $3,000,000 to $6,000,000.

THE SOUTH PORTO RICO SUGAR CO., 6 Cedar St., New York, N. Y., has disposed a bond issue of $6,000,000, for financing general operations, etc. F. A. Dillingha is president.

THE MESABI IRON CO., 25 Broad St., Ne York, N. Y., has arranged for an increas in capital from $33,000,000 to $53,000,000.

THE CALUMET OIL CO., El Paso, Tex has filed notice of increase in capital fro $50,000 to $150,000.

THE WILLIAM E. DEE CO., 30 North L Salle St., Chicago, Ill., manufacturer firebrick, tile, sewer pipe and other burne clay products, has filed notice of increase capital of $750,000 to $2,000,000, to cove the merger of a number of subsidiary com panies.

THE WAUGH CHEMICAL CORP., 2 Rect St., New York, N. Y., has filed schedul in bankruptcy with liabilities stated $211,276, and assets, $182,994.

Percival Wilds and Walter S. Wyma both of Augusta, Me., have been appointe receivers for the KENNEBEC PAPER CO. an the CUSHNOC PAPER CO., both of that cit under bond of $25,000 in each instance.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold twenty-fourth annual meeting at St. Lou Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold spring meeting at Birmingham, Ala., Ap 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY w hold its spring meeting in Baltimore, Ap 27, 28 and 29, 1922.

AMERICAN FOUNDRYMEN'S ASSOCIATIO will hold its next convention and exhibit Cleveland, O., during the week of Ap 24, 1922. Meetings will be held in t spring instead of in the fall as heretofo

AMERICAN INSTITUTE OF MINING A METALLURGICAL ENGINEERS will hold spring meeting in New York the week Feb. 20, 1922.

AMERICAN SOCIETY FOR TESTING M TERIALS will hold its twenty-fifth annu meeting June 26 to July 1, at Atlan City, N. J. Headquarters will be at t Chalfonte-Haddon Hall Hotel.

NEW JERSEY CHEMICAL SOCIETY holds meeting at Stetters Restaurant, 842 Bro St., Newark, N. J., the second Monday every month.

NORTHWEST MINING ASSOCIATION w hold a convention in the Chamber of Co merce Bldg., Spokane, Wash., Feb. 14 to

STAMFORD CHEMICAL SOCIETY, Stamfo Conn., holds a meeting in the lecture ro of the local high school on the fourth Mo day of each month, except June, Ju August and September.

The following meetings are scheduled be held in Rumford Hall, the Chemis Club, New York: Feb. 10—Americ Electrochemical Society (in charge), S ciety of Chemical Industry, Société Chimie Industrielle, American Chemi Society, joint meeting; March 10—Am ican Chemical Society, Nichols Med March 24—Society of Chemical Indu try, regular meeting; April 21—Soci of Chemical Industry (in charge), Ame can Electrochemical Society, Société Chimie Industrielle, American Chemi Society, joint meeting; May 5—Americ Chemical Society, regular meeting; May —Société de Chimie Industrielle (in charg American Chemical Society, Society Chemical Industry, American Electroche ical Society, joint meeting; May 19—Soci of Chemical Industry, regular meetin June 9—American Chemical Society, re lar meeting.

A Word To the Foolish

THESE words, alas, are designed for a gentleman who, probably, will never see them, because he does not read the chemical journals. He is in the chemical business, but not in the chemical profession. His money is in the works, but his heart is neither there nor in the laboratory. It is in the counting house. What we have to say to you, sir, is something you do not know. Your leading chemist, on whom you set such great store, wants to leave you. You can't understand why? Of course you can't, and we doubt if you could even if you were right here, sitting across the table from us. But now we shall make it harder still for you to understand. He is anxious to get another engagement even at a reduction of income. He is satisfied with the salary you pay him. In fact, you give him everything he asks for. His work, as work, suits him, and there is every reason to believe that it suits you.

Then what is the matter? We fear it is nothing you can remedy. You see, you are not as young as you were and your habits of mind are settled. You are a man of affairs, and that is a reputable calling. But although you are engaged in the chemical business you are not a chemist. To you chemistry means money, profit and sales, but it has not entered into your soul the way, let us say, your ambitions for your son have entered into your soul. You think, probably, that because the Doctor goes to the laboratory every day and draws his big check at the end of every month, he is satisfied. Well, now, we tell you, he is not satisfied at all. He has his dreams, just as you have yours. When he was young he heard his own tune sounded in the offing, and that was the call of chemistry, which he followed. He made good, and having done so you tendered him his present post, which he accepted. But because you are ignorant and narrow-minded and scientifically blind and deaf you can't understand that the call he heard was neither your whistle nor the clink of your coin. It was something infinitely bigger. It was the call of Science. It was the privilege, the distinction, to contribute something to human understanding. It was impersonal.

Now let us tackle the situation from another angle. That chemist of yours is dotty. He's got wheels. He wants to help humanity! Isn't that absurd? But that's his game. When he gave up pure science and embraced industry he thought that the larger purpose of industry was to augment human welfare, and that your dividends would come along on the side as some sort of honorarium. He never learned that antique slogan of yours that "Business is war." It never worried him to think that if information leaks out of the works, some competitor may profit by it, although you are very keen to forbid all communications that might lead to this. But it stands to reason that your competitors are in about the same position as yourself, and that they know some things that you don't. Slowly, whatever any one of you knows percolates through, and in the end the whole industry has it; but so long as you and your competitors are obstinate, the industry is retarded—seriously retarded.

We know some concerns that have given up having trade secrets. There are not many of them, but they are successful, and clear out of your class. Their chemists go to meetings and tell nearly everything they know, to the amazement of competitors who straightway profit by it. But they keep ahead of the game.

Don't you think it is about time for you to rest on your laurels and retire? Then you may get someone who knows the profession as well as the business of chemistry to take your place. That will raise the class of your whole institution. It will make for progress and even greater profit in the long run. But there's no use in trying to explain it to your directors. They don't understand, either. Like you, they are, scientifically speaking, ignorant men.

Mr. Ford and Muscle Shoals

WHAT will Mr. FORD do with Muscle Shoals if he gets it? Speculation has been rife for some time as to the purpose of the automobile manufacturer in acquiring this power and industrial project. Undoubtedly his primary interest is in power, because it will enable him to produce such metals as aluminum and magnesium, which might conceivably find extensive use in automobile manufacture. That he will make nitrogen fertilizer in some form or other is a part of his proposed contract with the government, though it is not expected that he will operate the nitrate plants solely along the lines for which they were designed and built. Phosphate fertilizer undoubtedly would be included in his program. Rumor has it that he will experiment with cotton for the production of a fiber board or similar material for automobile bodies, with the object of producing a car light in weight throughout its construction. All of these are rational proposals and would logically grow out of the acquisition of an industrial and power plant situated in a country that produces minerals and cotton.

Congress will soon have an opportunity to show whether it was sincere in disapproving the plan for the United States Fixed Nitrogen Corporation on the score that it did not believe in the government going into business and that it preferred to see the Muscle Shoals properties acquired and operated by private interests. We do not favor Mr. FORD'S proposal as far as it has been disclosed, for reasons which we have already set forth. It remains to be seen whether he has modified the objectionable items in the definite form of contract which he is understood to have signed.

Developing Chemists In the Industries

RECENTLY we have discussed several phases of the chemist's education as he obtains it in college. This is but the preparatory groundwork for the training that he will receive in his first few years of industrial experience, for it is in this period that he will usually discover his aptitude and fitness for his life's work. When he gets his first job in industry he cannot be sure at that stage of his training just what bent his ability will take nor what line of work he is most desirous of pursuing. If he chooses then, he does so blindly. He is likely to be influenced by a minor thing, by his admiration for some particular man who has been successful in his field or by the first job which offers an income. He is uninformed as to the range of opportunities. His college training usually will not help him to visualize the business world. But in order eventually to advance in the industry he must be able to picture in his mind the operations and processes in the manufacturing departments.

He can do no better then than seek a laboratory job in plants manufacturing heavy products from raw materials, such as acids, alkalis, coal products, metals, petroleum, oils, crude rubber or animal products. His choice among these is not so important, but may be governed by an estimate of the possible future growth of the particular one in question. If he has in the latter years of his college course been a consistent reader of technical and trade papers reflecting the economics of the technical industries, he will have some measure of information on which to base his decision.

These industries in turn may look upon their laboratory man as a raw material for other departments. While analyzing the materials, intermediate and finished products of the plant in his routine control or research operations, he must, by virtue of necessary contact with the processes and equipment, pick up considerable information on construction details, mechanical design, engineering features and business methods. He may be unobserving by nature, lazy of mind and learn very little, or he may be alert and obtain a large amount of information. His attitude at this point will largely determine his fitness to survive and develop in the field. The wise executive must eventually notice his bent and bring him into one of the departments as foreman, construction boss, engineer or efficiency man.

True, some plant managers are themselves lacking in ability to recognize human qualifications. In this case the alert chemist will seek employment elsewhere while either the manager or plant ultimately fails and falls behind in the business field; for the development of the human is far more important to the success of a business enterprise than any consideration of machinery or material.

Having eventually arrived at a better position in a department outside the laboratory, with the background of first a good character and second a technical education, the student rapidly passes the old-time operating man and is soon ready to become plant executive or salesman or fill some other coveted position. For he has now added to other experience the one most valuable of all—namely, a knowledge of the mechanism of plant apparatus and production. Knowledge based on actual physical contact with the things of industry and close association with the humans who work with them is the greatest essential to success in all branches. The salesman, for instance, can no longer succeed by a worship of the deity of well-turned words, better known as "hot air." For the salesman who is sure of his own knowledge and strong in his own heart must succeed. No argument coined by the keenest of buyers can disturb his solicitation.

Climbing then from the first step in industry as a laboratory man, up to the second as a "straw boss," and on to the third as a department foreman, the chemist of industry is standing where he may look over the nearer landscape and get a glimpse of the peaks of executive control beyond.

Does Business Want The Soldier Bonus?

OPPOSITION to the so-called soldier bonus proposed by Congress is admittedly an unpopular rôle to assume at this time. But the situation is fraught with such vital consequences to business and industry in this country that we deem it a reasonable duty to voice our protest against the scheme and point out its economic folly. At a time when thrift and economy have been urged upon the individual and promised by the dominant political party on behalf of the government, it is proposed, for reasons purely political, to fasten upon the country the burden of raising a sum estimated at not less than $1,500,000,000 and as much as $5,250,000,000.

This is proposed in the name of compensation for veterans who gave their services in the late war. We would be the last to deny those men any reasonable favor, courtesy or preference. But we are wholly unconvinced that the veterans as a whole are behind the demand for the bonus to which Congress claims it is bowing in submission. Approximately two million veterans went abroad and about two million more were in the service for 6 months' prior to the Armistice, making a total of about four million men under arms. Of these, 20 per cent, or 800,000, are in the American Legion, which is sponsoring the bonus on behalf of the soldier, claiming to represent his sentiment in the matter. But it is to be noted that four times that number of veterans are inarticulate as a body, to which we can add with certain knowledge that not all the American Legion favor the bonus.

Secretary MELLON has sounded a timely warning to Congress showing the necessity of reducing expenditures in order to balance the budget for the next fiscal year. Already there is in sight a deficit of $300,000,000 which must be met by either reducing our expenses or increasing our income. The adoption of the bonus plan would only aggravate this financial situation, because it would augment the deficit and necessitate still further taxation. Where is the money coming from? We cannot commit the folly of Europe and produce it on the printing press. We must raise it in cash by taxation. Subterfuges will avail us nothing. As for the American Legion, it dismisses the matter with neatness and despatch by observing that it is not concerned with the method of raising money.

Our own analysis of the situation leads us to believe that Congress will commit an economic blunder if it passes legislation for a soldier bonus. It will still further unbalance our national budget and delay the return to normal business conditions. It will add to the burden of taxation which it is pledged to lighten. And all this on account of political expediency and an unwillingness on the part of Congress to risk its precious politic

neck by standing for sound business as opposed to sentimental clamor. We admit there is some popular sentiment in favor of the soldier bonus, but we are inclined to believe that if the question were submitted to popular vote with the understanding that those who cast a ballot in the affirmative were at the same time to drop a $10 bill in the ballot box, the bonus would rapidly lose support. And yet a contribution of many times $10 will be levied on every voter if the legislation is passed. Business of the country should make a concerted effort to deter Congress from taking an unwise step, the consequences of which we shall suffer for many years.

Deflation in Coal-Mining Cost

ANNOUNCEMENT by coal operators of the Pittsburgh district of the wage rates they expect to pay after the termination of the present biennial scale of the United Mine Workers, which runs to April 1 next, furnishes occasion for study of the situation as to deflation of bituminous coal-mining costs.

While it is traditional that it requires two to make a bargain, the probabilities are that the wage scale now proposed will actually be effective without important modification.

For pick mining in the thin vein mines of the Pittsburgh district the proposed rate is 77 cents per net ton of mine-run, against $1.1164 in the existing scale, a reduction of 31 per cent. That is a moderate reduction, seeing that the high scale has diverted nearly all the business formerly enjoyed by the Pittsburgh district to nearby non-union districts, such as the Connellsville region, where wages have been deflated. The proposed rate is substantially the same as the 77.64-cent rate given the miners April 16, 1917, when the miners displayed an indisposition to work under the 67.64-cent scale signed as of April 1, 1916, for 2 years. The "pre-war" rate may be taken as the 64.64-cent rate obtaining for two biennial periods, April 1, 1912, to April 1, 1916. Back in 1896, when the men were paid on a screened coal basis, to keep down the production of slack, the rate was 54 cents, which by the ratio recognized some time ago would be equal to about 85 cents if the run-of-mine were paid for, as at present. Thus the proposed rate is more than double the rate of a quarter century ago.

Fears that there will be a serious shortage of coal on account of wage disputes by the United Mine Workers are probably unfounded, although there may be a strike with temporary disturbance of supply. These disputes have been very serious in the past. Reference to the large amount of time that has been lost by coal strikes in the 21 years 1899 to 1919 inclusive was made in CHEMICAL & METALLURGICAL ENGINEERING Jan. 4, 1922. Conditions now are different, however. One point is that mining suspensions in the past have sometimes been attended by advances in the market price of coal, making feasible the payment of wage rates in dispute, while no such policy would be countenanced now.

While only approximations can be made of the various factors involved, close enough guessing can be done to indicate that the United Mine Workers are not able to produce a mining suspension that would cause anything like an acute shortage of coal. Anthracite may be omitted from the reckoning. In bituminous coal the mining organization has hitherto controlled between 60 and 70 per cent of the mining capacity. The maximum production, 579,385,820 tons, in 1918, was well under the present capacity, being, say, between 80 and 90 per cent. The current requirements are only 65 or 70 per cent as great. Taking these factors together, it becomes evident that the current requirements could very nearly be supplied by the non-union capacity. It must be considered that some of the non-union capacity does not produce good coal, merely coal that is in demand when coal is very scarce, but it must also be considered that not a few mines have turned non-union recently, because the union scale did not enable the operators to meet the market, and the men wanted to work. And more of this may occur between now and April 1, and immediately after that date. Altogether, it seems fairly certain that there is going to be deflation in the cost of mining coal to something like a reasonable basis comparable with the cost of conducting other industrial enterprises involving the employment of labor. With deflation also in railroad and building trades labor, the country would be in fairly good shape.

Chemical Contribution To Agricultural Efficiency

THE Congressional commission of agricultural inquiry reported during December on causes of the agricultural crisis, and during the past month there has been a conference in Washington on the agricultural problems of the country at which these same matters have been publicly considered. But in all of the discussions there has been too great a tendency to subordinate or ignore altogether matters of efficiency in agricultural production.

The report of the Congressional commission presented about a dozen recommendations bearing upon co-operative combinations, credit extension, warehouse systems, freight rates, statistics, foreign trade attachés, grading of products, record keeping, better roads, price adjustments, etc. But it said almost nothing about those means which the chemical industries offer to agriculture for increasing production. A somewhat similar neglect of this question occurred in the public conference, though some attention was there given to the question of fertilizers.

Industry as it proceeds to organize itself almost invariably starts first at the point of production to get the maximum attainable efficiency before seeking support for its activities by auxiliary economic factors. In a few branches of agriculture this principle has been partly recognized and the use of fertilizer for increasing the productivity of the land is regularly and widely practiced. As a basic industry upon the welfare of which we all depend, agriculture stands in the first rank. No sound thinker dare ignore all of these economic factors which must be set right for the good of agriculture. But agriculture has a duty of its own in the management of its internal affairs. And the rest of the community may well insist that this responsibility for obtaining maximum productivity from given areas of land with a given expenditure of human labor shall be observed.

Agricultural chemistry has not yet reached the flower of its perfection, nor has the fertilizer industry yet taken advantage of all that chemistry has to offer in order to put it on a scientific basis. A vast amount of educational work has been done, but much remains to be accomplished in increasing the productivity of the soil before we can feel satisfied that economic aids will solve the problems of the farmer. First aid in the form of chemistry has not been sufficiently applied.

Readers' Views and Comments

Omnia Mutantur, Nos et Mutamur in Illis

To the Editor of Chemical & Metallurgical Engineering

SIR:—It was my fortune to be present at the Pittsburgh meeting of the American Chemical Society in 1902, referred to in your editorial of Jan. 18.

The "well-dressed chap" (he *must* have been well dressed if Dr. Baskerville thought so, although his clothes made no such impression on me) was waiting for us when we came out; he had his machine set up and invited some of us to inspect it. It was simply a microscope for observing the Brownian movement and we were excitedly urged to believe that the dancing particles were the atoms themselves. As I recall it, the man's announcement in the meeting was decidedly in the nature of an interruption, being addressed to the auditors generally and not to the chair. Dr. Remsen correctly sized him up as a crank and acted promptly and neatly in heading him off.

Oil-Shale Distillation in Situ in New South Wales

To the Editor of Chemical & Metallurgical Engineering

SIR:—The oil-shale industry of New South Wales is of long standing, having been started in 1865 by a short-lived enterprise which recovered oil from oil shale in the Kembla Valley in the southern coal fields. Following this a company distilled oil shale successfully for some years following 1878 at Hartley Vale, but oil recovery was later eclipsed by export of high-grade shale for gas enrichment, and finally exhaustion of the deposit caused the industry's discontinuance.

About 1905 the Commonwealth Oil Corporation came into existence, and £1,200,000 of capital was raised and expended, but the company has never paid a dividend. In July, 1919, this company entered into an agreement with John Fell, of Sydney, under which he is to operate the property for the joint account of the company and himself for a 10-year period, and at the present time the shale in the Newnes district is being worked under this agreement.

Now comes a report, published in the Sydney *Morning Herald* of Oct. 27, 1921, that Mr. Fell has succeeded in distilling oil from the shale in the Wolgan Valley by setting fire to the oil shale in an old working which has been so protected and confined by brickwork that the combustion can be controlled by regulating the supply of air. It is reported that, after starting the fire on a Monday, on Thursday, when the chamber was tapped, the amount of oil which flowed out exceeded the available storage capacity.

The experiment seems to have great significance for the Australian oil-shale industry, as the costs of mining and retorting the oil shale and of refining the crude oil have exceeded the landed cost of American petroleum products, and the industry has been enabled to survive only through a graduated bonus paid by the commonwealth government on home-produced oil. Other possibilities of gas and power production have been opened up by Mr. Fell's experiment which will be further developed.

It is interesting to note that the idea of gasifyin and distilling materials *in situ* is an old one,[1] althoug this seems to be the first large-scale trial made wit promising results. It should be borne in mind that th experiment here reported was carried out with the ric "kerosene shale" of New South Wales, and it is n probable that many of our American shales could b treated by similar methods, even though the principle d distillation *in situ* should prove successful in the com monwealth.

To Assist Legitimate Users of Industrial Alcohol

To the Editor of Chemical & Metallurgical Engineerin

SIR:—Because of the difficulty various manufacturer have experienced in obtaining their requirements o alcohol for industrial purposes the Committee on Indus trial Alcohol of the American Chemical Society believe it advisable to call to the attention of manufacturers th fact that there is such a committee and that this com mittee stands ready to co-operate with them in ever possible manner. This service is without any expens to those who require this essential chemical raw mate rial.

During the past several months manufacturers re quiring alcohol for legitimate industrial purposes hav been experiencing many difficulties. Numerous change in rules and regulations and the issuance of new one have caused considerable delay and expense.

The Committee on Industrial Alcohol was appointe at the Rochester meeting of the American Chemica Society. This committee offers its services to the chem ical industry to assist in obtaining permits, shipments etc.

Chemical manufacturers who wish to take advantag of this offer should communicate with the chairman o any member of this committee. Their names and ad dresses are as follows:

Dr. Martin H. Ittner, chairman, Colgate & Co Hudson St., Jersey City, N. J.

Dr. Raymond F. Bacon, 50 East 41st St., New Yor City.

Dr. Charles Baskerville, College of the City of Nev York, New York City.

Dr. George F. Rosengarten, Powers, Weightman & Rosengarten Co., P. O. Box 1625, Philadelphia, Pa.

Dr. Frank R. Eldred, Eldred & Atkinson, Inc., 48 E 41st St., New York City.

Dr. Edward Mallinckrodt, Jr., Mallinckrodt Chemica Works, St. Louis, Mo.

Dr. Burnell R. Tunison, secretary, U. S. Industria Alcohol Co., 27 William St., New York City.

It is believed that publicity to the above statemen will be appreciated by manufacturers who may be bene fited by the services of the committee.

New York City. B. R. TUNISON.

[1] On "Gasifying Coal at the Mine," see Hamor, *Scientific Amer can* for Nov. 2, 1912. A number of patents have been issued o various schemes for distillation and gasification of various ma terials *in situ*, among which are U. S. Pat. 1,342,741 to David T Day, and British Pat. 162,337 (1919) to D. Diver.

The Technical Paper and Its New Relation to Industry*

In Order Better to Fulfill Its Functions of Service and Leadership the Modern Technical Paper Has Extended Its Scope of Usefulness and Supplemented Its Technology With the Economics and Business of the Industry It Serves

By H. C. PARMELEE

[F WE ATTEMPT to analyze the elements that have contributed to the evolution of modern civilization in all its variety and complexity, we are likely to ome to the conclusion that the most powerful single orce has been the rapid development in means of com- unication among individuals, communities, cities and ations. To such a degree of perfection have these eans been developed, and so complete has been their onquest of conditions on our own earth, that intrepid ioneers are already attacking the problem of interworld ommunication.

Great industries have been founded in the course of ese developments. Ships sail the seven seas to the ttermost parts of the earth; railroads cover the con- nents like networks of steel; aircraft cruise their outes regularly with incredible speed; the telephone nd telegraph are known in the humblest village; radio ommunication is almost a commonplace; and finally the roducts of the printing press have long since lost the lement of novelty and are accepted as an integral part f our daily life. These agencies have brought about ne great transition from primitive society in which uman intelligence was transmitted by word of mouth. hey have at once simplified and complicated modern fe; simplified it by bringing the peoples of the earth nto closer contact, and complicated it by extending our elationships and increasing our duties and obligations. hey have unified nations in war for a great cause, and ney have given an impetus to peaceful industrial rowth unparalleled in the history of the world.

Development of Civilization Dependent on Printing

But though all these agencies have contributed largely o the development of modern society, it is certain they ave not been of equal value and importance. Ships, ailroads and aircraft may be developed ever so highly nd yet be limited as means of communication if they ransport only men from place to place. Important as re the telephone, telegraph and radio in the quick ransmission of intelligence to and from all parts of the orld, they are still restricted to communication between xed points and a small number of individuals. Obvi- usly some other agency in combination with these has een responsible for that wide distribution of human nowledge and intelligence that characterizes modern ociety and which has been responsible for its develop- ent. Some other means has been evolved to reproduce or thousands and millions of individuals the product f the world's great intellects and lay it regularly be- ore all who want it. It is in the discovery and perfec- on of printing and paper that we find the essential ement in all this marvelous development. Modern ivilization, said Lord Avebury in addressing an inter- national gathering of paper manufacturers, depends upon the discovery of cheap paper and rapid printing for the wide distribution of information.

This we may accept without demanding exhaustive proof, for it requires no stretch of the imagination to visualize the influence of printing on the wide dissemination of knowledge. By this means industrial, political and economic information has spread with amazing rapidity. By it the intelligence of one nation has become the property of the whole race, and the intellect of a great leader has been able to influence the trend of thought of the entire world. In short, we may accept the press as the means of communication par excellence, and proceed to examine one of its comparatively small but important branches—namely, the industrial press, that has just begun to sense and exercise its power.

Growth of the Industrial Press

Industrial publishing has reached its highest development in the United States, where more than 1,200 periodicals are now devoted to industry in all its phases. The growth of this great publishing business has been coincident with the industrial expansion of the country itself. The first industrial paper of which we have record in this country was founded in 1846. In the next decade two more were established, but no great impetus was given to the business until after the Civil War, when the country went through its marvelous period of growth and development. Industries of all kinds invited leadership, and industrial magazines sprang up to point the way. The result was that from one paper in 1846, three in 1856 and twenty-five in 1869, the number grew to 800 by the end of the century and to well over 1,200 at the present time. Including Canada, it is estimated that there are in America between 1,200 and 1,400 industrial publications, the number varying with the method of classification.

An important group of the industrial press comprises what are known as technical papers because they deal with the technology of industry, with the application of science and engineering principles to the problems of production and management. It is in this group that you, as chemists, are most interested, and since both you and I have a still narrower interest in technical magazines devoted to the chemical industry, we may confine further observations to papers of that class.

My topic, "The Technical Paper and Its *New* Relation to Industry," suggests a contrast with an earlier relation, and so we may go back for a moment and sketch that former relation briefly in order to emphasize the new order that must be expanded and developed if the technical paper is to live up to its opportunity for service and leadership.

Technical papers for the chemical and allied industries are of comparatively recent development in this country, but if we examine the early files of such papers

*An address delivered before the Chicago Section of the American hemical Society, Nov. 18, 1921.

we will find that they were devoted almost strictly to matters of technical interest. They recorded the results of scientific research and investigation and of progress in the arts. Processes and products were discussed in their scientific and technical aspects. The contributions were of a high order of merit, and the contributors were recognized scientists of learning and ability. On the whole the publication was maintained on a high plane of scholarship and was a credit to the profession. Its reliability and integrity were above reproach and its subscribers bore testimony to its value and influence in all technical matters. It was a tool of the profession rather than of the industry.

The *raison d'être* for such a magazine is not far to seek. It was a product of its time and it served its purpose well. Technical industries were in a state of rapid evolution, and the latest developments in technology were of primary importance. It was essential that the scientific foundation of industry be carefully laid in order that the superstructure might endure. In short, industry being more interested in, and most in need of, technical leadership and guidance, the function of the technical paper was plainly to serve along these lines.

New Responsibilities for the Technical Paper

But excellent as this service was, and adequate though it proved for its time, it will not suffice today. New elements have entered into our national industrial life and by presenting new problems to industry have at the same time laid new and additional responsibilities on the technical paper. It is no longer enough for it to treat of technology; it must consider the business and economic problems of industry as well. The technical paper can no longer fulfill its function if it merely discusses processes and products; it must also be the business exponent and mouthpiece of its industry, reflecting its needs and guarding its interests. It must become an integral part of its industry, serving all its needs. It must be of the industry as well as for it.

The perception of this new responsibility was quickened during and immediately after the war, when we faced industrial and economic problems that far transcended in importance the problems of technology. The Government itself was confronted with industrial problems of the greatest magnitude, and as a result of the war was involved in the most intimate relations with business and industry. There was the greatest need for some public agency to reflect the needs of industry to the Government and to interpret the intentions and acts of the Government to industry. In this condition industry found itself without a mouthpiece or exponent unless the technical press threw itself into the breach, which it promptly did.

Washington became a great center for technical and industrial news, requiring the closest daily contact on the part of the business press; and as a consequence of the early recognition of this fact, industry was served with pertinent Government news through its technical papers.

The necessity for this arose mainly from the fact that the daily press in all its excellence was not equipped to meet the need. It was not and could not be intimately familiar with the details of industry, and consequently could not sense its needs. The whole country was face to face with a brand new crop of problems, and since industry had learned to follow its own technical papers in matters of science and technology, it naturally turned to the same source for leadership in these new conditions. The technical paper promptly sensed and accepted the situation. It became a magazine of opinion on labor problems, on the tariff, on wages, the cost of living foreign trade, Government policies, the patent system revenue legislation and finance and many other matters formerly regarded outside its editorial scope. It discussed industrial waste in all its forms: the necessity for better cost accounting, for greater safety in industry, for improved housing and sanitation, for more skillful management, for more research. It expressed its opinion on the regulation of business by the Federal Trade Commission and the Interstate Commerce Commission. It took up industrial relations between employer and employee and devoted much space to the numerous phases of that many-sided subject. It spoke with authority and competence on such matters as reorganization of Government departments because some of its editors had been drafted from Government service and knew whereof they spoke.

These things were invaluable because they reflected to the industry the opinions of men familiar with the industry itself and sympathetic with its needs. Speaking from a chemical point of view, it was not enough to discuss the technology of the industry; somebody had to present the economics as well. For example, coincident with the technical problem of fixing nitrogen was the question of Government ownership and operation of nitrate plants and its effect on business. Of quite as much importance as how to make dyes was the question of establishing an industry in the face of foreign competition. The tariff was a paramount issue. We had the brains for dyemaking, but we needed the economic basis for an industry without which our technical brains would avail us nothing. The alcohol industry likewise was, and is, much more concerned with fanatical legislation than with methods of manufacture. All of these things were consistently presented in the technical press for the benefit of industry and the education of Government officials.

Technical Press Supplies Industry With Vital Statistics

In the matter of new development there was the constant necessity of keeping the economic and industrial as well as technical aspect clearly in mind. For this reason the technical press has brought to industry vital statistics on consumption and production, on imports and exports. It has shown the close relation of plant location to industrial success. It has featured the importance of markets for new products and sources for raw materials. It has acquainted industry with pertinent activities of the Government, sometimes approving and sometimes condemning.

In its relation to the Government the technical paper has been constructive and helpful. Witness its service since the war in aiding in the disposal of surplus property; in suggesting new uses for materials held in large quantities by Government departments; in discussing the function of the Government in research; in advocating reform in the Patent Office; in supporting the Chemical Warfare Service and creating public sentiment that resulted in establishing this branch of the service on a scale somewhat commensurate with its importance.

Probably the greatest stimulus to this new function of the technical press as an intermediary or connecting link between the Government and industry was the action of Mr. Hoover inviting the editors of the business

press of the country to assist him in solving many of the problems with which he was confronted in the Department of Commerce. This was at once the greatest recognition of the importance of the industrial press and a challenge to prove its usefulness by showing its intimate knowledge of industrial matters. What body of men in the country should be better able to reflect to the Government the needs of industry, and carry to industry the story of the Government's intention to aid and assist rather than hamper and restrict? So argued Mr. Hoover, and accordingly the memorable Hoover editorial conferences began in Washington last spring.

Technical Press as an Aid to Government

They have resulted in laying before the Secretary of Commerce plans for elimination of waste, for standardization of sizes, types and styles of industrial products, for correlating the bureaus and agencies in his department and making them function more directly for the benefit of industry. They have resulted in the first effort ever made in this country to publish monthly vital statistics on consumption, production and stocks of critical commodities in the basic industries. Finally, they have been helpful in the reorganization of the Department of Commerce by finding men from the industries to head the new commodity divisions that have been created. And all of these things, mark you, have been done by technical industrial papers that formerly devoted themselves wholly to matters of science and technology, because they have seen clearly the need of this new service to their respective industries. Much of the best work has been done quietly through committees, questionnaires and researches, but it has been none the less effective. Mr. Hoover has generously recognized the value of this service in a message to the editors in which he said in part:

> The editors of the business press have shown a fine spirit of service. Your opportunity for leadership is unique and unchallenged. Upon you rests in large measure the responsibility of the control of industrial thought and opinion in the detail of the industrial, economic and technical problems which confront us.

I have mentioned the inadequacy of the daily press in presenting to industry such matters as have just been discussed. They are essentially technical and hence not within the grasp nor the province of the daily newspaper. They will not be adequately presented for business and industry except through the medium of the industrial press. This is no reflection on the daily press, but merely a recognition of its limitations and the consequent need for the industrial press. We may consider a few examples.

Examples of Technical News Service

As an industrial disaster the explosion of the nitrate plant at Oppau, Germany, was of such magnitude as to interest the entire world. And due to its marvelous mechanism for transmitting intelligence, the daily press gave us immediate reports of the occurrence. But the explosion had a far greater and deeper significance to chemical industry, and in all its attempts to give precise information that might be helpful the daily press failed utterly due to its manifest limitations. Not only did it fail as a purveyor of precise, accurate and reliable news of the event, but it exemplified the blind as leaders of the blind in its editorial comment. So great a newspaper as the New York *Times* drew the conclusion that German chemists had been experimenting with new and deadly gases, in violation of the terms of the treaty, and had wrought their own destruction through their discoveries. It called upon the Badische company to show clean hands in the matter, and it looked frankly with suspicion on the whole affair. Mystery surrounded the explosion and consequently mysterious conclusions were drawn as to its cause and significance. The press dispatches having said that the disaster was due to "the decomposition and subsequent explosion of a large quantity of ammonia and sulphate of saltpeter," the *Times* suspected "experimenting of a secret nature," and thought it "not inconceivable that the disaster at Oppau may have been due to covert experimenting by those chemists." All of which was of no help or consequence to the chemical industry, and it devolved upon the technical press through its enterprise and intelligence to inform the industry of the facts as nearly as they could be ascertained.

Examples might be multiplied. Chemical warfare was first condemned in the daily press, and first supported by the technical paper. Reports of such conventions as President Wilson's first industrial conference and the recent unemployment conference were more reliable and pertinent in the industrial than in the daily press, for the reason that the latter was inclined to feature spectacular incidents and subordinate substantial accomplishments.

All of these things are in the nature of a service to industry and the public welfare now performed by the technical press. It is not spectacular, but far-reaching. It influences the intelligent leaders of industry to blaze the way to new reforms, initiate constructive policies and establish sound principles and practices in industry.

This service to industry by the technical press is a leaven that eventually leavens the whole of society. Through the leadership of the technical magazine in its own industry, it spreads information and serves as a clearing house for new ideas that eventually are translated into economies for the benefit of society as a whole. The service to industry is direct, and to society indirect.

Functions and Standards of the Technical Press

From this general portrayal of the activities of the modern technical paper we may proceed to summarize its functions in industry and study the mechanism through which they are performed.

1. The modern technical paper is still a magazine of information pertinent to the technology of the industry it serves. This is an important function that cannot be subordinated without jeopardizing industrial progress. Economies resulting in cheaper production must still be worked out through scientific research and the application of the results in the factory. But this is not service enough.

2. The modern technical paper also treats of the economics of its industry, informing its readers on the relation of the tariff, finance and other legislation to business.

3. It is the newspaper of its industry, gathering weekly the items of personal and business intelligence on which its readers should be informed. Market movements and trade tendencies are reflected in reports gathered at first hand. Foreign as well as domestic news is obtained regularly by cable and wire.

4. The modern independent technical paper is a magazine of opinion—the mouthpiece of its industry. And herein lies one of the distinctive differences be-

tween it and the technical society magazine. The editorial independence of the industrial paper, its freedom from domination by any interest or allegiance to any group, make it possible to adopt policies in the interest of the industry as a whole. Obviously this is denied to the society publication, which must serve primarily its own membership. Editorial opinion cannot be expressed with freedom on a wide variety of topics for the evident reason that the magazine must speak for the society. An independent industrial technical paper, on the other hand, labors under no such handicaps, being bound only to serve the best interests of its industry whether people agree with it or not. If subscribers do not like its policy they need not take the paper.

5. The modern technical paper sets a high standard of business ethics and practice in its industry. Both in its business and editorial departments it subscribes to a code of ethics that has been adopted by associations of business publishers and industrial editors. These standards are high and must be subscribed and adhered to by members of the association.

Enforcing Its Code of Ethics

The technical editor is pledged to consider first the interest of his subscriber. Truth and honesty must characterize his every activity. He is obligated to present the news of the industry free from personal bias and to determine the editorial contents of his paper independently of advertising considerations. The publisher also sets a high standard of business practice in the acceptance or rejection of advertising and in publicity regarding the character and extent of his circulation.

Periodical investigations are made to see that members are living up to these standards. This is one of the most powerful factors in making the technical paper a leader in its industry. With its own skirts clean it can consistently demand that its industry be free from unfair practices. Having adopted a high code of business ethics for itself, it can, both by precept and example, urge similar action upon its industry. The adoption of a code of editorial ethics and business practice has been of the greatest benefit in establishing the independence of the technical paper.

Recognition as an Essential Element of Industry

The exercise of all these functions results in a service, first to industry and then to society, that makes the modern technical paper an essential element of industry. It was so regarded by the Government during the war; and it must be self-evident that in times of peace publication of knowledge and intelligence is indispensable to the development of industrial literature. What then is the mechanism for exercising these functions? The answer is found in the editorial staff. And just as the technical paper's new relation to industry requires a broader service, so the modern editorial staff comprises a wider range of talent. In many respects it resembles a college faculty, being composed of men who are specialists in their respective branches of technology and industry. Papers covering the chemical and allied technical industries find it particularly necessary to have comparatively large staffs of qualified scientists, technologists, economists and industrial experts. They are called upon to judge the competence of articles that form our technical literature. They are expected to reflect sound opinion on matters of public policy in relation to their industries, and to take the lead in safeguarding those industries from ill-advised legislation or private practice. They must display enterprise and initiative in discovering sources of news and information so that their industries may be kept abreast of development. And it goes without saying that in addition to their ability they must be men of integrity with a keen sense of editorial ethics.

Editors Must Maintain Close Contact With Their Industries

Nor can these things be accomplished without close personal contact with the industry itself. Travel by the editors is a *sine qua non* of successful industrial journalism. Conventions must be covered and reported in their essential features, for hundreds and thousands of men are unable to attend and must rely on the published record for their information. That this service is appreciated is attested by the correspondence following the publication of convention proceedings, asking for more detail or further information. Plants must be visited and processes described in order that text book fundamentals may be amplified and brought up to date with practical details of current practice. In short, the modern technical paper cannot be edited from the desk, but it must show a familiarity with industry itself that is acquired only by personal contact. The consequence is that the industrial editor is enabled to see his industry as a whole and judge it impartially. This was strikingly exemplified at the last National Conference of Business Paper Editors in Chicago, when a résumé of conditions in ten basic industries was presented by as many editors of industrial magazines. These reviews were authoritative and could not have been pictured better, if as well, by industrial leaders themselves.

Relations to the Industry and to the Individual

Such, then, is the new relation of the technical paper to industry as seen by the technical editor. Such is the duty of the industrial and technical press, as well as its opportunity for service, as conceived by the publishers. It results in a service that is growing more and more expensive, but which yields results to industry that more than justify publishers' outlay. No single industrial unit could afford to maintain for itself the service thus rendered to industry at large. It is a service that is destined to be expanded rather than contracted, just as industry itself becomes more complex and needs broader vision and leadership.

This evolution holds its lesson also for the individual. Just as the technical paper must supplement its technology with the economics and business of industry, so must the individual broaden his scope in order to find his greatest usefulness. Science will never develop its greatest usefulness to society as long as it is translated into technology only. It must find expression also in sociology, in economics and in the management of industry. This will call for broader training and more diverse talents among scientists, some of whom will continue to enrich the records of research while others develop managerial ability or technical superiority or acquire skill in the practical application of economics and sociology. The ultimate aim—for the individual as well as for the industrial press—will be the perfection of our industrial processes, the elimination of waste, the stabilizing of labor and production, so that human happiness and standards of living may be increased. To such an end the modern technical paper is dedicated.

Colloidal State in Metals and Alloys. IV—Iron and Steel

Atomic Dispersion of Carbon in Austenite Is Unlikely, but Martensite, Troostite, Sorbite and Pearlite Contain Carbide Particles of Increasing Size—Martensite and Other Dispersions of Critical Size Are Hard Because of Enormous Surface Tensions Associated With Fine Grain*

By JEROME ALEXANDER
President, Uniform Adhesive Co., Brooklyn, N. Y.

THE enormous literature that exists regarding the iron-carbon alloys exhibits at once their great importance and exceeding complexity, and within the brief limits of this paper only a few of the most striking facts can be dealt with. Since the behavior of the iron-carbon alloys is greatly influenced by the allotropic changes of iron itself, it will perhaps be best, first, to consider what these are, according to the evidence available.

Allotropy of Iron

After freezing at about 1,505 deg. C., pure iron, upon further cooling, shows a large evolution of heat at about 900 deg., known as the thermal arrest point Ar_3, and a smaller evolution of heat at about 780 deg., known as the thermal arrest point Ar_2. It is generally accepted as a fact that above 900 deg. the iron exists in the γ from, which is non-magnetic, and below 780 deg. in another allotropic α form, which is magnetic and exhibits a different crystallization from γ iron. Rosenhain believes[1] that the weight of evidence shows that between 900 and 780 deg. the iron exists in a third allotropic form, known as β iron, which has the same crystal form as α iron, but resembles γ iron in being non-magnetic. Benedicks,[2] on the other hand, believes that the evolution of heat at 780 deg. indicates, not a transformation of a β allotrope into α iron, but the final disappearance of persistent γ iron molecules from the metal.

Considering the recent work on the allotropism of sulphur, it seems that these apparently conflicting views can be reconciled by regarding the iron between these temperatures (900 and 780 deg) as an allocolloid or allodispersoid, the so-called "β iron" being an α-γ adsorption compound (α iron dispersed in γ iron), whose break-up into the more completely oriented α iron sets free the relatively smaller amount of heat at the point Ar_2. This view accounts for the following facts: (1) that "β iron" has the same crystal form as its "dominant partner," α iron, but, unlike it, is not magnetic—for magnetism seems to depend upon a peculiar regular molecular orientation[3]; (2) that γ iron dissolves iron carbide, whereas "β iron" and α iron do not; for whatever γ iron exists in the β zone is adsorbed by or in some kind of loose combination with the dominant α iron and is not free to exert its solvent power on iron carbide; (3) that an increase in strength is noted when α iron is transformed into "β iron"; for the formation of some γ iron by increase of temperature over about 780 deg. results in the formation of the α-γ adsorption compound, which increases the free surface and strength of the system; (4) that the structure of "β iron" is finely acicular, indicative of crystallization in the presence of a colloid.

Does Austenite Contain Molecular Carbon or Cementite?

Leaving this moot question, however, let us consider the behavior as noted in the equilibrium diagram, Fig. 1, of a low-carbon steel, containing, say, 0.2 per cent of carbon, which dissolves in the liquid iron as Fe_3C. From freezing down to 840 deg. this steel consists of an apparently homogeneous "solid solution" or dispersion of iron carbide or cementite in γ iron.

[In a recent paper[4] entitled "The Slip Interference Theory of the Hardening of Metals" Jeffries and Archer state:

> "There is good reason to believe, however, that in all cases solid solutions are characterized by the *atomic* dispersion of their components." This is true only if the expression "solid solution" is limited to such dispersions; but most solid solutions contain aggregates, just as do many or even most ordinary solutions, especially if concentrated. Jeffries and Archer further state that "the carbon in austenite is present as individual atoms of carbon"; that "these atoms are undoubtedly held strongly to the neighboring iron atoms, but the union is not permanent. Diffusion must consist in a migration of carbon atoms and not of groups or 'molecules' containing several iron atoms. Such groups could not, on account of their size, diffuse through solid iron."

It seems to the present writer that there is no good reason to doubt the existence of Fe_3C, especially when the steel is semi-solid or solid. For there exists a condition of kinetic or dynamic equilibrium in which this compound is being continually formed and broken up, so that while a certain per cent of free carbon atoms may exist at any one moment, there is probably an enormously larger percentage of Fe_3C. Viewed from the standpoint of a kinetic equilibrium, all difficulty regarding the diffusion of Fe_3C disappear.[5]

With large amounts of carbon, as in cast irons, much of the C is thrown out on cooling and forms graphite, or under conditions of quick cooling or high pressure may form diamonds, as Moissan has shown.]

At any rate, at 840 deg. C. (Ar_3), the "solid solution" transforms into a α-γ dispersion ("β iron"), and at 750 deg. C. (Ar_2), the residual α-γ adsorption compound decomposes into α iron, the steel now consisting of α iron crystals dispersed in a "solid solution" of iron carbide in γ iron. With further cooling, the quantity of α iron crystals increases, until at a little below 700 deg.

The present series of papers was written mainly in the fall of 1919. Reduced to about half their original form, they were read before the Columbus meeting of the American Institute of Mining and Metallurgical Engineers, October, 1920, and will so appear in vol. 64 of its *Proceedings*. They are now given in full, together with some recent additions which are indicated by enclosure within square brackets [ ].

*Part I, on Molten Metal, appeared in Chemical & Metallurgical Engineering, vol. 26, p. 54; Part II, on Crystallization, in vol. 26, p. 119; Part III, on White Metal and Brass, in vol. 26, p. 170.

[5] See also p. 1065 of Jeffries and Archer's paper.

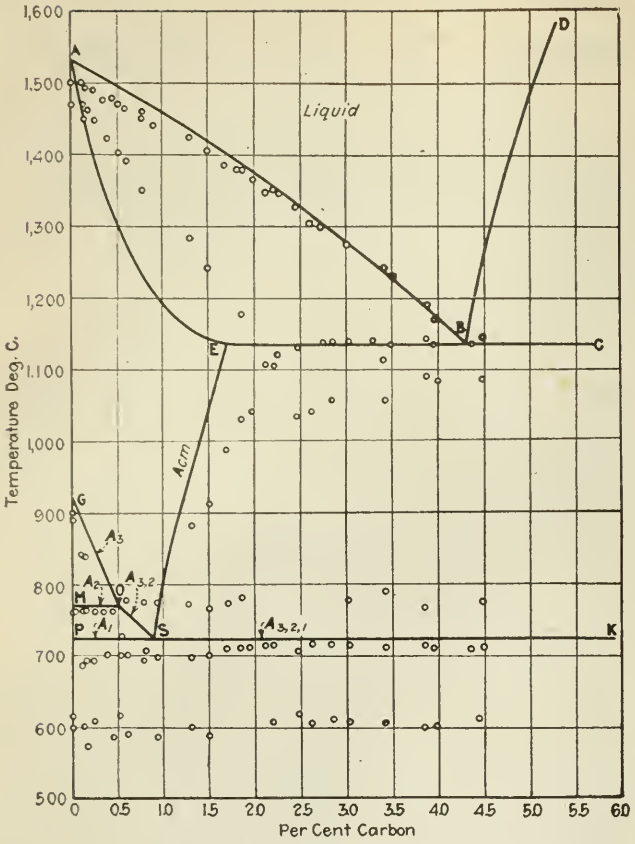

FIG. 1. EQUILIBRIUM DIAGRAM OF THE IRON-CARBON SYSTEM (AFTER HOWE. POINTS FROM CARPENTER AND KEELING)

C. (Ar_1), the remaining γ iron-carbide solid solution is transformed into a eutectoid mixture of α iron (ferrite) and iron carbide (cementite), with an evolution of heat.

Reactions at 690 Deg. C.

This last transformation seems to be the break-up of an adsorption compound between γ iron and iron carbide, the former transforming into α iron and the latter being set free to form aggregations of its own. This adsorption compound is the cause of the carrying over of some of the γ iron through the so-called "β iron" zone to the eutectoid point, where, with increasing carbon content, increasing quantities of heat are evolved, the allotropic transformation of the iron itself becoming practically negligible after the steel contains about 0.5 per cent carbon (equal to about 7.5 per cent Fe_3C). In fact, steel of "eutectoid composition" (about 0.9 per cent C, or about 13.5 per cent Fe_3C) exhibits only a single thermal arrest point, at which it glows visibly. This phenomenon is known as "recalescence"; it is indicative of a sudden large release of energy consequent upon the breakdown of the extensive metastable system built up of γ iron and cementite, two delayed transformations occurring simultaneously—the iron transforms from γ into α and at the same time the released cementite aggregates. The inhibition of the allotropic iron transformation shows that in eutectoid steel the large percentage of Fe_3C has carried over practically all the γ iron in metastable condition to the eutectoid point. The presence of such elements as silicon and manganese will perceptibly change the location of the eutectoid point, a fact which fits in with the easy disturbance of colloidal systems by foreign substances or "impurities."[6]

But whether this view is accepted or whether the charge is regarded as a separation of carbide from "γ iron solid solution," one thing is certain—there is suddenly released from some kind of solution or combination Fe_3C, an insoluble substance possessing considerable cohesion, which promptly causes it to attempt to aggregate against the interference offered by the now highly viscous iron. This is an ideal condition for the development of a colloidal system; but the cohesive power of the cementite is so great that in unquenched steel it usually appears as shown in Fig. 2*b*, interspersed with α iron, or ferrite, as fine plates or fibrils, yielding the finely laminated structure known as "pearlite" because under proper illumination it exhibits the iridescent luster of mother of pearl. This iridescence, reminding one of that of a diffraction grating, is evidence of the fineness of the pearlitic structure, which, like Pleurosigma, taxes the highest powers of the microscope for its successful resolution, the lamellæ being often less than 0.2μ apart.

Divorce of Cementite

As shown microscopically in Fig. 2, after Rawdon, eutectoid steel (approximately 0.9 per cent of C) when slowly cooled consists entirely of pearlite, thus corresponding to the pure eutectic of ordinary alloys.[7] But with very slowly cooled steel, or with steel reheated for a long time at about 900 deg., the cementite tends to group up still further into balls or globules, the liberated ferrite forming larger crystals at the same time (Fig. 2*d*).

The cementite when present as isolated balls or lumps is of very little use to the steel, which then possesses merely the properties of pure ferrite having a coarse structure—these, of course, being far from equal to those of a mild

[6] In the presence of protective colloids, insoluble salts (i.e., $CaCO_3$) become more soluble in water.

steel having the correct structure. . . . When in the condition of pearlite or sorbite, where cementite is intimately associated with layers of ductile ferrite, the inherent brittleness of cementite is largely neutralized, and the hardness of the duplex consituent—pearlite—is well adjusted to stiffen and support the ferrite matrix of a mild steel. Cementite of itself, however, is not only excessively hard and brittle, as compared with ferrite, but it is also too small in quantity and bulk to serve as an efficient stiffener. Its presence in the isolated state thus becomes a source of weakness rather than strength. The behavior, both under test and in service, of steels having this "free cementite" structure is now well recognized as most unsatisfactory. (Rosenhain, p. 278.)

Quenched or quickly cooled steels, on the other hand, exhibit an entirely different set of microscopic pictures and mechanical properties from slowly cooled steel, which vary with the speed of chilling. Arranged in order of their formation on progressive cooling, the following constituent forms of the iron-iron carbide dispersion are recognized by metallurgists:

Nature of Structures in Hardened Steel

Austenite. White, apparently structureless γ iron solid solution, when preserved as such down to ordinary temperatures, either as the result of quenching or by the presence of a third alloying element inhibiting its decomposition—i.e., manganese in manganese steels.

Martensite. The first stage in the aggregation of the γ iron solid solution; the hardest constituent of hardened steels; it varies widely in the details of its structure, but is mainly acicular (Fig. 3).

When steel has been quenched from very high temperatures[8], the martensite is found to occur in large grains showing a rather coarse acicular structure. When, on the other hand, a steel of eutectoid composition is quenched at a temperature just above the critical point Ar_1, then the structure of the resulting martensite is exceedingly fine—so fine, indeed, that some workers, not perhaps provided with the best of microscopic appliances or employing unsatisfactory etching methods, have failed to detect the acicular structure, and have claimed that the best hardened steel contains a structureless "martensite," which they have sometimes distinguished by the term "'hardenite"—a purely local term whose general use is not to be recommended. The careful examination of samples of the best and most carefully hardened steels, however, has convinced both the author [Rosenhain] and the majority of impartial observers that martensite can always be shown to have an acicular structure, although in "properly hardened" steel that structure is exceedingly minute. (Rosenhain, p. 179.)

Troostite. A dark-etching constituent (Fig. 3) with characteristic rounded or woolly outlines, found particularly in hypo-eutectoid steels at the edges of martensite grains, especially where they border on ferrite. By a suitable rate of cooling, or by proper tempering, martensite can be entirely converted into troostite.

FIG. 3. MARTENSITE (LIGHT) AND TROOSTITE (DARK), AFTER HANEMANN. × 450

It is sufficient for our present purpose to regard troostite as a further step in the degradation of austenite into ferrite plus pearlite. The dark color appears to be due to the condition of the carbon in this stage; the separation of the dissolved carbide from the iron must have begun as soon as the first particles of γ iron became transformed into the β or α condition. In the martensite stage the separation makes itself felt only very slightly by the small difference of color between the various systems of interlacing needles. When the troostite stage is reached we are probably dealing with a material in which the separated iron carbide is present in slightly larger masses. According to Benedicks[9], the carbide in troostite is present as a colloidal suspension[10], and it is quite probable that troostite differs from martensite only by the slightly greater segregation of the carbide particles. (Rosenhain, p. 183.)

In the paper by Benedicks cited by Rosenhain, the Swedish scientist remarks:

> After studying some of the colloid literature, it was entirely clear to me as far back as 1905 that the nature of troostite is simply explained; it is a *solid colloidal "solution" of cementite in iron (a solid cementite ferrosol).* In other words, troostite may be conceived of as a highly dispersed intermediate between martensite, the true solid solution, and pearlite, the coagulum. . . . Troostite is a pearlite in which the constituent particles are ultramicroscopically small.

With steel containing 1 per cent carbon, Benedicks obtained the following results, the test-pieces being cylinders 50 mm. long x 6.5 mm. in diameter:

Temperature, of Steel, Deg. C.	Time of Cooling to 100 Deg. C. Seconds	Result of Microscopic Examination
950	3.07	Only martensite
848	4.32	Only martensite
750	4.11	Only martensite
715	5.33	Martensite with traces of troostite
695	6.2	Martensite with traces of trocstite
725	9.5	All troostite

The last specimen had been wound with 1 mm. iron wire so that its weight was increased from 12.3 to 27.5 g., thus lengthening the cooling period. From this it is evident that the speed of aggregation is so great that within a few seconds all the martensite may be transformed into troostite.

Sorbite

When the rate of cooling is further lessened or the temperature of reheating or tempering is further increased, the steel is permitted to progress somewhat further toward the final state of ferrite plus cementite. Instead of the troostite described above, we find a constituent still devoid of any visible detailed structure under the highest available magnifications (Fig. 2*a*), but not etching to such a deep color as troostite and without the peculiar rounded outlines. This is often called "sorbite," but it may be regarded as simply a variety of pearlite in which the two constituents are so finely divided that they cannot be microscopically separated. The dividing line between pearlite and sorbite, indeed, is simply a question of microscopic resolving power. (Rosenhain, pp. 182, 184.)

Pearlite. This microscopically resolvable dispersion of Fe_3C in ferrite has been previously dealt with.

Before discussing the facts above stated it will be convenient to tabulate the main features:

TABLE I. NATURE OF STRUCTURES IN HEAT-TREATED STEEL

Iron-Cementite Dispersions	Nature of Dispersion	Crystal Structure
Austenite	"Solid solution"	Structureless streaks.
Hardenite	Colloidal	Structureless martensite.
Martensite	Colloidal	Generally acicular; varies, may be very fine. (Fig. 3.)
Troostite	Coagulation begun	Rounded or woolly (globulitic), Fig. 3.
Sorbite	Coagulum	Fine pearlite, not microscopically resolvable. (Fig. 2a.)
Pearlite	Coagulum	Laminated; may seggregate into balls. (Fig. 2.)

Fig. 4, taken from Prof. H. C. H. Carpenter's paper on "The Hardening of Steel,"[11] shows graphically the

[8] The higher the temperature before quenching, the longer the cooling time, and therefore the greater the degree of aggregation.

[9] *J. Iron and Steel Inst.*, No. 2, 1912; *Koll. Zeit.*, vol. 7, p. 290 (1910).

[10] As will be seen later, in troostite the cementite particles have already grown almost or quite beyond the colloidal stage. In martensite, however, some of the carbide is so fine that the carbon released by the action of acid is reduced by the nascent hydrogen, forming a variety of hydrocarbons.

[11] *Engineering*, vol. 107, p. 341 (March 14, 1919).

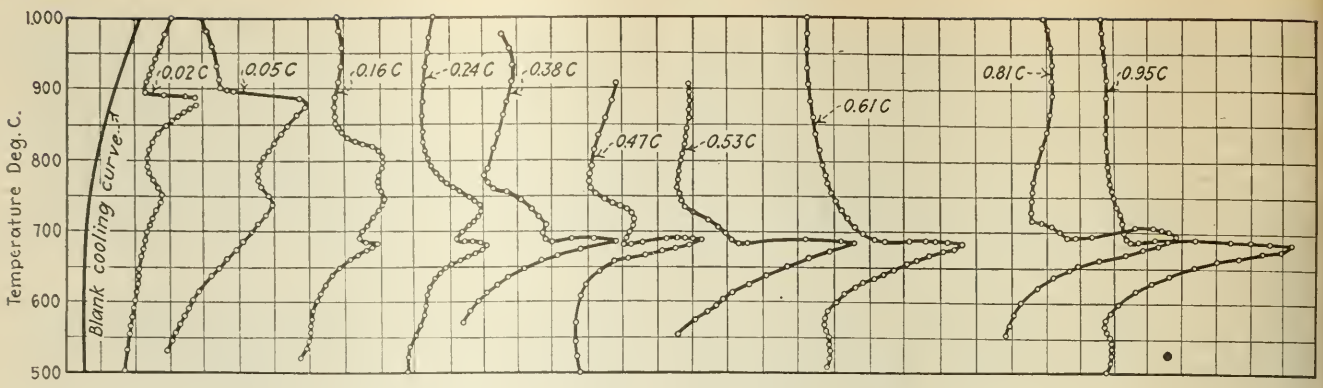

FIG. 4. COOLING CURVES OF IRON AND IRON CARBON ALLOYS

changes in the thermal arrest points in steel with gradually increasing carbon content, the point Ar_1 appearing at about 0.16 per cent C, and growing, while Ar_2 and Ar_3 diminish, until in eutectoid steel they have disappeared.

Granting that in austenite the cementite is in true molecular dispersion, which I consider very doubtful especially after solidification has begun, it seems evident that, of the remaining members of the iron-cementite dispersion systems, martensite and troostite are to be regarded as within or approaching the colloidal zone of dispersion, whereas sorbite and pearlite are coagula of the pre-existent colloidal systems, the latter visibly so. In the colloidal systems martensite and troostite,

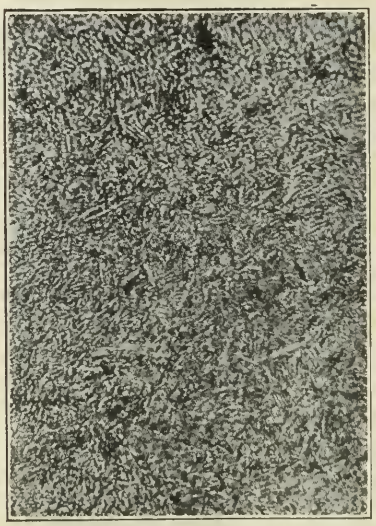
TABLE II. CONDITION OF STEEL AT VARIOUS TEMPERATURES

Pure Iron	0.2 per Cent Steel	0.9 per Cent Steel
γ Iron.....	γ iron-cementite solid solution.	This is eutectoid steel. So much cementite is present that no α-γ adsorption compound is formed, the γ iron being held in met stable condition by the cementite, down to Ar_1.
900 deg. C. γ iron forms α-γ adsorption compound (β iron). (Ar_2) Largest thermal point.		
	840 deg. C. (Ar_3) α-γ compound or β iron forms late because of cementite.	
Allocolloidal Zone		
	750 deg. C. (Ar_2) α-γ compound (β iron) changes to α iron.	
780 deg. C. α-γ compound (β iron) decomposes into α iron. (Ar_2)		
	700 deg. C. (Ar_1) γ iron-cementite "adsorption" compound decomposes, γ iron changes to α iron, and cementite is liberated and aggregates.	700 deg. C. ($Ar_{2,1}$) Sudden change of all the iron from γ to α, with liberation of all the cementite.
α Iron.	α iron and cementite.	Pearlite.

cementite (Fe_3C) is the dispersed phase and iron the dispersing phase; for this is shown by the nature of the pearlite coagulum, which consists of cementite interspersed in ferrite. In martensite, crystal formation is only incipient, inhibited by the high viscosity of the dispersing medium, and perhaps also by the adsorption of a small residual quantity of γ iron (consequent upon lag in its transformation), or of impurities. With troostite the globulitic stage is reached, often found in crystallization inhibited by colloids, and reminding one somewhat of the "clumping" of typhoid bacteria in the Widal test. It must be remembered that metal surfaces etched by various reagents are artifacts, from which the original detail of the unetched metal must be inferred.[12]

Variations in Dispersions

Athough theoretically there is no sharp line of demarcation between any of the members of the iron-cementite dispersion series, the sorbite-pearlite group shows the characteristics of coagulated colloids or gels, as opposed to the martensite-troostite group which represents higher dispersion, with troostite already appreciably on the road to coagulation. With milk, upon great dilution, the gradual aggregation of the actively moving ultramicroscopic particles of the casein sol may be watched in detail over a period of half an hour or more.[13] The ultramicrons first form occasional groups of two ("diplococci") and then larger and more numerous groups, until finally the whole casein lies quiet on the slide in large grape-like masses of curd, which under dark field illumination show the reticulated structure characteristic of such gels, and remind one forcibly of very fine martensite (Fig. 5), which, however, usually registers the high crystallization tendency present in its constituents, but absent in casein. The positive inhibition of the coagulation of the casein by "protectors" (gelatin, gum arabic, sodium citrate) may also be visually demonstrated. With clays, too, similar differences in aggregation may be noticed,[14] especially "diplococci" and the retriculated structure. But with metals, owing to the dense concentration of their particles, the rapidity of the changes and the high temperatures at which they occur and the practical impossibility of obtaining transparent sections[15] without disturbing the *status quo*, it will probably be impossible to settle moot points with



VERY FINE MARTENSITE IN QUENCHED MEDIUM STEEL. × 500. (RAWDON)

the ultramicroscope alone. Perhaps, as before indicated, the X-ray spectroscope will aid, small pieces or drops of fluid metal being drastically quenched in liquid air or other liquid gas; or an ultramicroscopic examination of gold, silver or other metal leaf or mirrors, or of films of mercury or amalgams; or the solution of metal by a differential solvent, in the presence of a "protector."

[Jeffries and Archer[16] report preliminary results with the X-ray spectrometer as follows:

(1) Non-magnetic steels show face-centered cubic lattices (γ iron).

(2) Magnetic steels show body-centered lattices (α iron).

"A 1.5 per cent C steel quenched from above the critical in iced brine showed both martensite and austenite under the microscope, and the X-ray spectrometer pattern showed both face- and body-centered lattices. A 0.35 per cent C steel quenched from above Ac_3 showed only martensite under the microscope and only a body-centered lattice with the X-ray spectrometer." These results confirm the views above expressed, and, as the authors state, they indicate that the transformation from austenite to martensite represents a substantially complete change from γ to α iron. They further show that quick chilling may save some of the iron in γ form. As Benedicks' work[9] shows, the speed of transformation is very rapid, so that only by the drastic chilling of small specimens as above suggested will much of the γ iron be maintained. Interesting results can be obtained, no doubt, with low melting point metals like mercury, gallium, and with Wood's and Rose's alloys, by quick chilling in liquid air, CO_2 or N, being followed by X-ray examination while cold.]

Hydrocarbons Formed on Dissolving Martensite

Meanwhile there is other distinct evidence of the colloidal nature of the cementite in hardened steel. Prof. H. C. H. Carpenter, speaking first of annealed or slowly cooled steel, says:[11]

> This carbide can be separated from the steel by appropriate solvents which remove the iron. On the other hand, it is not possible to separate any carbide of iron from a properly quenched tool steel. When the latter is treated with dilute acids, the steel dissolves without residue and liberates a complicated mixture of hydrocarbons, both liquid and gaseous. There is, therefore, a fundamental difference in the form of the carbide in a quenched as compared with an annealed steel. In the former it is wholly dissolved, in the latter wholly segregated.

This last statement is too dogmatic, and Prof. Carpenter, evidently appreciating the truth of the adage quoted by Ramsay, *Natura nihil fit per saltum*, retrieves it by continuing:

> When hardened steel is softened by annealing, the carbide of iron is gradually precipitated. If the annealing be carried out at low temperatures it is precipitated in the form of ultramicroscopic particles which are known as troostite. On raising the temperature the troostite passes into another variety known as sorbite, and at still higher temperatures well-segregated pearlite results. The gradual tempering and softening of hardened steel is caused by the precipitation of iron carbide in these forms, together with the soft α iron, and as to this no difference of opinion exists.

The formation of hydrocarbons upon the solution of hardened steel in acid shows that the particles of Fe_3C are so small that upon their decomposition the nascent hydrogen is able to combine with the liberated carbon, which must appear in particles approximating molecular dimensions and within the range of molecular attraction. The variety of hydrocarbons formed is evidence of the great diversity in the size of the carbide groups rather than of the existence of a number of different carbides, or "chemical compounds"—in other words, the carbide in properly hardened tool steel exists almost entirely in colloidal form. Great chemical activity is generally consequent upon colloidal dispersion—thus Raffo and Pierni showed that, while fine precipitated sulphur does not affect silver salts in the cold, and and does so only partly upon boiling, colloidal sulphur reduces them energetically even at ordinary temperatures. Fine lead, produced by heating dry lead tartrate in a tube, takes fire instantly in the air, as does the phosphorus left upon the evaporation of the solvent CS_2 or ether.

Colloids Prevent Tree-like Crystals

The strong tendency of metals to form adsorption compounds, especially when their molecules are aggregating, and the ease with which their crystallization forces may then be controlled are readily shown by a simple experiment.[17] A solution of lead nitrate is divided between two glasses, to one of which is added a "protector" (gelatin or gum arabic solution). On introducing into each glass a strip of metallic zinc, the pure nitrate solution promptly develops large glistening crystals of metallic lead—the well-known "lead tree"—whereas the protected solution yields an amorphous looking black deposit, which microscopic examination shows to consists mainly of aborted crystals, dendrites and globulites. The characteristic dendritic crystals of lead have elongated arms or processes, which in an interlocked mass may easily be mistaken for acicular crystals. I have also produced similar dendrites of iron by depositing the metal in the presence of a protector. Particulars regarding this will be given later in a paper on the effects of colloids on crystallization. The use of colloids to produce fine grain in the electrodeposition of metals is now familiar to you all.[18]

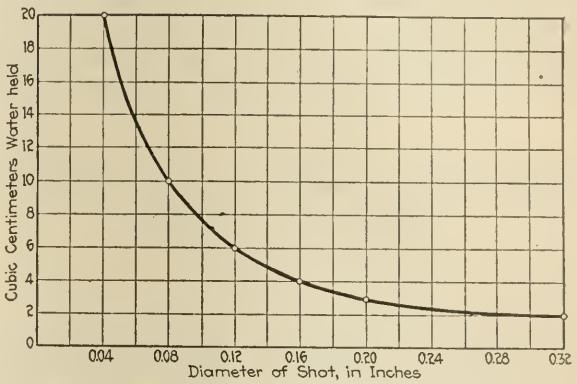

FIG. 6. RELATION BETWEEN DIAMETER OF SHOT AND VOIDS

The consequences of fine subdivision are far reaching, affecting solubility (Hulett), fusibility (Doelter), chemical activity, electrical conductivity (Fink), vapor tension, solution pressure, specific gravity, adsorption, including adsorption of gases, and energy content (Graham). The most striking results are consequent upon the enormous development of free surface. Thus

TABLE III. RELATION BETWEEN SIZE AND SURFACE AREA OR VOIDS

Grade of Shot	Dia., In.	No. per Oz.	Unit Area, Sq.In.	Area per Oz., Sq.In.	Vol. per Lb.	Water to Cover	Water Retained
Dust	0.04	4,565	0.005	22.8	76 c.c.	28 c.c.	20 c.c.

a cube of 1 cm. edge has a total surface of 6 sq.cm. (0.93 sq.in.); but if cut up into colloidal cubes of 0.01μ edge there would be a million million million such cubes whose combined surface area would be 646 sq.ft. (93,000 sq.in.).

The following simple experiments show to the naked eye some of the effects of subdivision with consequent increase in free surface. Uniform weights of several standard sizes of lead shot (1 lb. each) were measured in a 100-c.c. cylinder, just covered with water, and what water would leave the shot was poured off. Table III and Figs. 6 and 7 show the results.

Colloidal Dispersions Are Hard

Thus the amount of water held by the shot is substantially a linear function of the area, and will probably vary somewhat with the nature of the surface of the globules. While chemical attraction in the ordinary sense is out of question here, Bechhold has shown[19] that adsorption varies greatly with the chemical nature of the adsorbent. With the finest shot ("dust") the surface forces, adhesion and adsorption, are already great enough to cause the wet shot to "clump" or stick together noticeably, and we get an inkling as to the power and extent of the enormous forces called into

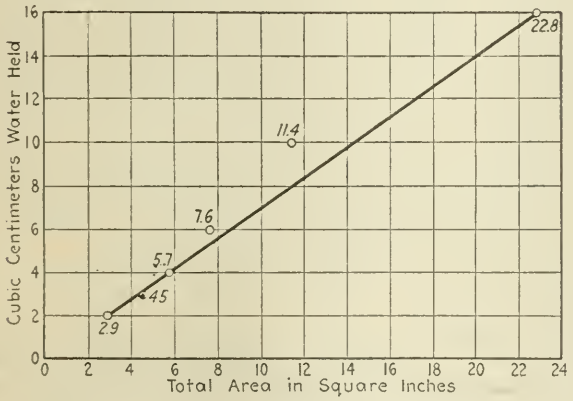

FIG. 7. RELATION BETWEEN AREA OF SHOT AND VOIDS

play by a great development in free surface. It is only natural, therefore, that colloidal dispersion should bring with it a great increase in hardness in metals.

Waiving the question as to whether the cementite in austenite is colloidal (and I think that at least as the steel freezes it becomes so), it seems that the very hard martensite is a colloidal dispersion of cementite in iron, a cementite ferrosol, with "hardenite" as its higher dispersion, troostite its incipient globulitic aggregation product, and sorbite and pearlite its successive coagulation stages. This view will perhaps reconcile the "allotropic" and "amorphous" theories which have been advanced to answer the question as to the constitution of martensite and the cause of its great hardness. According to the former,

> The hardness of martensite is due to the presence in it of a notable proportion of "hard" β iron. . . . the acicular structure of martensite would be due to the formation, on the cleavage planes of the originally homogeneous γ iron solid solution, of needles of β iron. Normally such β iron would be obliged to expel the carbon which it had held in solution before the transformation, but, during quenching, time for such separation would not be available, and the β iron would be compelled to retain in "forced" solution, or in very fine suspension, the carbon thus unavoidably retained *in situ*. The "amorphous" theory also explains the hardness of quenched steel by postulating the existence of an intrinsically hard but unstable transition product, which is formed when the transformation of the homogeneous γ iron solid solution into ferrite and carbide is hindered by quenching. Instead of identifying this hard substance with β iron, which has only a short range of stability in iron and low-carbon steels, the new (amorphous) theory ascribes hardening to the presence in the steel of amorphous layers similar to those which are believed to be the cause of the strain-hardening of ductile metals.[20]

Considering martensite as a cementite ferrosol, a colloidal dispersion of iron carbide in iron, it is "amorphous" in the sense that its particles, even if actually crystalline, are mostly not microscopically resolvable; and, especially in low-carbon steels on quick chilling, there is a tendency to carry over into the solid state some of the α-γ allocolloid or "β iron," so that the iron-dispersing phase itself may represent a colloidal dispersion, consisting mainly of minute α iron particles.[21] And because of the highly colloidal nature of the martensite and the consequent great development of free surface in it, it is extremely hard. Large percentages of oil colloidally dispersed or emulsified in water yield very firm stiff masses, although both phases are liquid.

[Jeffries and Archer[22] say:

> There is no conceivable way in which a few per cent by volume of a strong constituent in disconnected particles could impart a new element of cohesion of the magnitude actually obtained. Their action must consist in rendering more effective the cohesion latent in the aluminum. The logical inference is that this is accomplished by the elimination of extended planes of weakness—that is, by slip interference. . . . Under the action of an external load tending to produce slip along these planes, the hard particles of $CuAl_2$ must act as *keys*, mechanically obstructing any motion along the planes as a whole.

This mechanical comparison will undoubtedly appeal to engineers, but *the action of surface forces*, together with fineness of crystal grain (which in itself reduces the length of any one plane of slip), are quite sufficient to account for the phenomena observed. In making putty the addition of a few per cent of oil makes a viscous, "strong" mass with whiting; the finer the "filler" the stiffer the mass it makes with the same amount of oil—i.e., the more oil it "takes." Again, as S. V. Pickering[23] showed, 99 per cent of petroleum oil emulsified in 1 per cent of soap water makes an extremely stiff mass.

These illustrations indicate that a few per cent even of a *weak* constituent may produce relatively great hardness, *provided that it is very finely dispersed.* (See also discussion of the abbreviated form of the present series of papers by Prof. Le Chatelier and my reply thereto—*Proceedings*, Am. Inst. Mining and Metallurgical Engineers, vol. 64.)

This is quite contrary to what Jeffries and Archer state on page 1063: "We should not expect *soft* particles to produce hardening, because the 'keys' of soft substance would shear and thus assist rather than oppose slip. The term *soft* is used here in the relative sense only." Now, oil and water are certainly soft and scarcely act as "keys" that prevent slip in the cases above referred to. We must remember, however, that substances which are fluid *in mass* need not be so necessarily when finely subdivided. Thus the more

finely divided mercury is, the more it seems to act like a solid. With increasing subdivision, surface forces ordinarily negligible predominate.[24]]

Maximum Hardness Occurs at Less Than Maximum Dispersion

The fact that austenite, though harder than pearlite, is not as hard as martensite, indicates that the latter represents a point, or rather a zone, of maximum degree of colloidality[25]—that is, there appears to be a certain degree of subdivision or dispersion, not necessarily the same with all substances, in which the dispersion system exhibits colloidal or surface phenomena to the highest extent, this effect declining not only with increasing aggregation or coagulation, but also with further peptization and the approach of true molecular dispersion, or the formation of smaller molecules.

[Jeffries and Archer in their paper on "Slip Interference"[26] designate the point of maximum hardness as the "critical dispersion." It had been referred to by Merica, Waltenberg and Scott.[27] In the preliminary paper on the zone of maximum colloidality referred to above,[25] it is stated:

The *viscosity* of reversible, emulsoid, or hydrophile colloids, one of their marked characteristics, sometimes increases as the dispersed phase becomes *finer* (as in oil emulsions, homogenized milk) or sometimes as the dispersed phase becomes *coarser* (as with soaps, night-blue, butyric acid). In fact there seems to be with each dispersion a *zone of maximum colloidality*, above which viscosity decreases with coarser subdivision as the Brownian motion becomes sluggish (about 100$\mu\mu$), and below which it also decreases as molecular dimensions are approached (about 5$\mu\mu$), and the Zsigmondy-Brownian motion becomes violent. This zone has approximate limits and a crest or peak not necessarily the same with various substances—indeed we should expect specific variations[28].

The approach toward the zone of maximum colloidality from the side of coarse dispersion is illustrated by clays which hold increasing amounts of water as their particles become smaller. The approach from the side of molecular dispersion is illustrated by the experimental results of Martin H. Fischer[29] on the sodium salts salts of the fatty acids. The sodium salts of formic, acetic, propionic, butyric and valeric acids always give molecular dispersions with water. Sodium caproate (with 6 carbon atoms) begins to show signs of "holding" water, while the caprylate (with 8 carbon atoms) gives a jelly when one mol is mixed with 250 c.c. of water. With the higher acids in the series the water-holding capacity per mol of sodium soap increases rapidly as the molecules become larger: capric (C_{10}), 500 c.c.; lauric (C_{12}), 4 liters; myristic (C_{14}), 12 liters; palmitic (C_{16}), 20 liters; margaric (C_{17}), 24 liters; stearic (C_{18}), 27 liters; arachnic (C_{20}), 37 liters.

The appearance of a zone of maximum colloidality is not limited to the so-called emulsoid colloids. Thus with steel the Fe_3C-Fe dispersion reaches its maximum hardness in martensite, and becomes softer if the dispersion becomes greater (austenite) or less (troostite, sorbite, pearlite). A similar zone of maximum hardness exists in the dispersion of copper aluminide ($CuAl_2$)[27]].

The behavior of hypoeutectoid steels (containing less than 0.9 per cent C) is naturally complicated by the fact that the transformation of the excess γ iron (that in excess of the γ iron-cementite adsorption) into α iron, or the break-up of the α-γ adsorption ("β iron"), takes time and exhibits a lag which is most marked in the quickly cooled specimens. On the other hand, with hypereutectoid steels (containing more than 0.9 per cent C) the excess of cementite tends to crystallize out in slowly cooled specimens and to yield some undecomposed γ iron-cementite "solid solution" in quickly cooled ones. To consider these in detail, and also the high-carbon "cast iron," would unduly extend the limits of this paper; but I must comment on the observations of McCance,[30] who showed "that on adding carbon to iron, the hardness of the quenched steels increases up to 0.7 per cent C, and remains constant between this point and 1.18 per cent." This indicates a zone of maximum colloidal effect, which probably covers the zone of maximum degree of colloidality above referred to. The addition of manganese to steel, as Maurer has shown, retards the aggregation of the cementite so that ordinary slow cooling yields martensite, probably because the viscosity of the dispersion medium (iron) is increased by the manganese (melting point, 1,225 deg. C.), which by its surface or adsorptive action acts like a protector in opposing the aggregation of the martensite constituents; on the other hand, the manganese increases the speed of the transformation, when it finally does occur, because the manganese exerts its force then in the direction of the readjustment. Still larger percentages of manganese prevent any transformation at all, yielding austenite.

Lignite Carbonization—Carbonized Residue Briquets*

By W. W. Odell

Fuel Engineer, Bureau of Mines

Of recent years interest in the development of lignite fields and the production of beneficiated fuel has become more general or widespread, simultaneously with the increase in price of high-grade fuel. Not only is it recognized that our supply of high-grade anthracite is limited, but cognizance is taken of the fact that in many localities the average quality of the fuel now being purchased is not so good as that bought under the same name a number of years ago. This difference is primarily due to the increasing amount of incombustible material that is permitted to pass into a coal shipment as coal. The natural result of this higher ash content and resulting lower heating value, in conjunction with a higher price for such fuel, is that the clean lower grade fuels automatically become relatively more valuable.

The development and utilization of low-grade fuels is not new, but on this continent conditions have not heretofore been favorable to such enterprises. The abundance of the available supply of lignite in this country in locations where other fuel is obtainable only by a long freight haul from distant sources has made the lignite problem a serious one for domestic consumers in such localities as the Dakotas and Texas.

For many years it has been recognized by Dr. E. J. Babcock, dean of the mining engineering department of the University of North Dakota, that the solution of the lignite problem is of vital importance to the state of North Dakota, and to the development of certain industries in that state. The studies made under his guidance include briquetting the raw lignite, briquetting the dried and partly carbonized lignite, drying and

carbonizing lignite in rotary driers, horizontal retorts, beehive ovens, kilns and inclined ovens.

If briquets are made simply from dried lignite, other complications are met with in handling the material, such as the strong tendency for the dried lignite to ignite spontaneously. Also, the dried lignite does not lend itself well to briquetting. The conclusion reached in the studies by Dr. Babcock was that the best manner of producing a highly beneficiated fuel from lignite is to briquet a carbonized residue. The aim in general is to produce a fuel for domestic use which, on combustion, will liberate the greatest amount of heat per unit weight of fuel compatible with an economic method for its manufacture. It is appreciated that a fuel approaching anthracite may be desired for some purposes, whereas briquets capable of giving a longer flame on burning are desired for other uses. The problem as taken up at the University of North Dakota is naturally divided into two phases: First, the carbonization of lignite, so as to make a suitable material for briquetting, and second, the briquetting of the carbonized residue with the minimum amount of a suitable binder to form a firm, resistant and even-burning fuel.

Experimental Plan

During the past summer (1921) experiments were conducted at the Hebron, N. D., substation under a co-operative agreement between the University of North Dakota and the U. S. Bureau of Mines, for the purposes of ascertaining what results might be expected commercially from a particular type of oven; what methods of control should be used; what yield of gas, tar and ammonia might be realized, and to learn more about the design of a carbonizer best suited for lignite. It is obvious that in erecting or designing a complete plant it is necessary to know the capacity of a unit carbonizer as well as that of the briquetting equipment, and in order to produce the finished product at the lowest possible cost, it is desirable to obtain the maximum capacity in the operation of the carbonizer. These and other important details were given particular consideration during the co-operative tests.

The plan of the work was to carbonize approximately 1,000 tons of raw lignite by continuous operation of the carbonizer, briquetting the residue into a firm, solid fuel, and to obtain meanwhile as many data as possible relating to the following:

1. Quality and quantity of gas obtained. 2. Quantity of gas required for carbonizing. 3. Behavior of lignite during processing. 4. Capacity of carbonizer. 5. Quality and quantity of residue obtained under various conditions. 6. Analyses of lignite, residue and the briquets made therefrom. 7. Binder requisites. 8. Character of briquets made. 9. Control methods. 10. Cost of briquetted residue. 11. Quantity of byproducts. 12. The design of apparatus suitable for carbonizing lignite.

This program was adhered to as nearly as possible throughout the experiments.

Various types and styles of retorts and carbonizers have been in use at different times during the previous investigations made by Dr. Babcock and associates at the University of North Dakota and the substation, the present construction being their most recent result of the continued study of the characteristic properties of lignite, and its behavior when heated.

The carbonizer used during the co-operative tests consisted of twelve inclined retorts (a double row of six), as shown in isometric perspective in Fig. 1. The upper ends are open, and a pile several feet high, of raw lignite, is maintained above them. The carbonized product is drawn off periodically from the lower ends, after being partly cooled by contact with the air ducts or recuperators at the bottom of the setting. Exhaust steam is used to complete the cooling, and is supplied so as to be in contact with the residue at the time it is discharged into the conveyor beneath.

The gas liberated is taken off into a hydraulic main (not shown in Fig. 1), where a uniform seal is maintained so as to keep a uniform and controllable pressure condition in the retorts. An exhauster draws the gas from this main and forces it through a cooling system, where the tarry vapors are removed, and on to a manifold supplying gas to heat the retorts. The gas is supplied to the lower flues, and preheated air is used for its combustion.

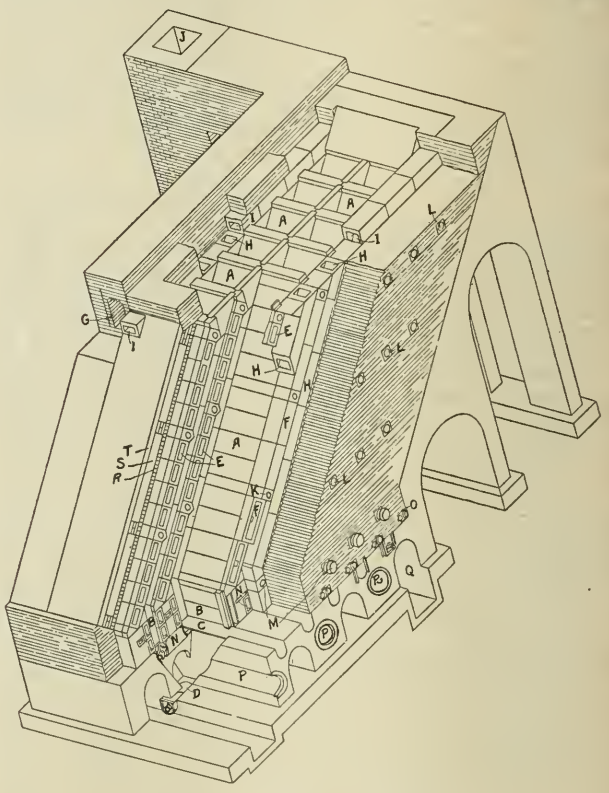

FIG. 1—LIGNITE CARBONIZER

A Inclined chambers. *B* Cooling chambers. *C* Discharging device. *D* Screw conveyor. *E* Heating flues. *F* Heating flues (end sections). *G* Waste heat flue. *H* Heating flues at sides of chambers. *I* Header for flues *H*. *J* Stock. *K* Gas offtakes, openings to chambers not shown. *L* Gas offtake blocks to receive iron pipes. *M* Poke holes. *N* Preheating flues for secondary air. *O* Dampers for secondary air supply. *P* Manholes. *Q* Tunnel for cross-conveyor. *R* Firebrick (set rowlock). *S* Ashes. *T* Reenforced concrete.

The capacity of such a carbonizer depends on the kind and quality of lignite used, as well as on operating conditions, size of retorts and other variables. Twenty tons per day of raw lignite was carbonized in this particular unit.

The briquetting equipment would briquet 2 tons of mix per hour. Belgian rolls were used, with 22-in. face, three rows wide, giving a pillow-shape briquet weighing approximately 2¼ oz. The briquets obtained held up nicely in the fire, burned evenly, and withstood severe tests.

A complete report of the results obtained during the experiments is now in preparation by the co-operators.

Some New Petroleum Products*

The Vapor-Phase, Low-Temperature, Catalytic Oxidation of Fuel Oil and Other Crude Petroleum Fractions Is Shown to Yield a Series of Novel Chemical Products Which Appear to Have a Broad Range of Possible Industrial Applications

By J. H. JAMES
Professor of Chemical Engineering, Carnegie Institute of Technology

VERY little chemistry enters into ordinary petroleum refining, the process on the whole being based on physical principles. Where chemistry is introduced at all, as in acid agitation or sulphur removal by the Frasch and other processes, it is only for the purpose of removing certain substances, the presence of which impairs the value of the main product. The "cracking" processes developed in recent years are, however, an exception to the foregoing statement, for they involve chemical changes. The various commercial products of petroleum in present-day practice are those mixtures of hydrocarbons, the sum of which made up the greater part of the original crude.

The purpose of this paper is to describe in rather brief outline some work done in an attempt to prepare certain new chemical products by starting with petroleum as the raw material. The industrial application of the products thus obtained appears to belong in part to the oil industry and in part to industries decidedly remote. The fundamental idea of the process involved is the vapor-phase, low-temperature, catalytic oxidation of the aliphatic hydrocarbons of the petroleum.

While references are numerous in the literature to the many attempts made to oxidize petroleum hydrocarbons in the liquid phase, the first recorded work in the vapor phase appears to have been that of Walther.[1] Walther's apparatus, his arrangement and selection of catalysts and his temperature (he worked at a glowing red heat), as well as his air ratio (which must have been very high, as he maintained self-sustained combustion) all show, as our experiments have proved, that his proposed process was bound to be a failure. In the one experiment cited in his patent, he claims to obtain a liquid of lower boiling point than the original material treated, although his description of the other products is noticeably incomplete.

Selection of Catalyst and Temperature Control

The author has found that the first requisite for success in obtaining yields sufficiently high and of satisfactory quality for industrial use is the selection of the catalyst. In this connection the oxides of certain metals of high atomic weight and low atomic volume, such as molybdenum and uranium, appear to be the most promising. Where compounds of closely related metals can be formed, such as diuranyl vanadate, very good results were obtained.

Numerous experiments have shown that many oxides have catalytic activity in this connection, but it is believed that for commercial development, all things considered, the best selection is within the group noted above. Good results have been obtained by passing the mixture of hydrocarbon vapor and air through a thin layer of uranium oxide and then on through two layers of catalyst consisting of the oxides of molybdenum. The reason for the three catalytic layers, or, as we call them, "catalytic screens," will be noted later. The uranium oxide is used in the first screen because this oxide has the specific property of catalyzing to a marked degree the aldehydic stage of oxidation, so that where acids are desired as the main product, this preliminary step brings about a higher yield of acids, the aldehydic bodies going over to acids in the second and third screens.

In this process the temperature at which any reaction between molecular oxygen and aliphatic hydrocarbons begins is about 240 deg. C. Owing to the fact that the oxidation is slight at this temperature, and also to the further consideration that more heat is required to vaporize heavy hydrocarbons even with air, or air and steam present, higher temperatures than this must be employed. In general, the temperature should be as low as is consistent with good vaporization and a sufficiently rapid reaction; this varies of course with different petroleum fractions, but in any case no results of industrial value can be obtained above 500 deg. C. The writer's experience here would dictate that rather than work at temperatures approaching such a figure (where very high molecular weight hydrocarbons are being treated) it is better to run a small amount of the heavy petroleum fraction—such as wax distillate, for example—with a large amount of a fraction of lower boiling range, such as gas oil or heavy kerosene, thereby effecting ready vaporization of the heavy portion and allowing a lower catalyst temperature for the reaction.

Although steam may be used with good results, too much steam hinders the reaction, so that with very heavy fractions it will not do to depend entirely on steam as an aid in vaporization.

Some Products of the O idation

The products formed vary somewhat with the catalyst and the temperature employed, but in general represent all the stages of the oxidation of aliphatic hydrocarbons from alcohols to oxygenated acids, together with hydrocarbons and oxidized bodies resulting from secondary reactions. These various bodies have not been studied in detail, but the acidic portion has usually been separated and the non-saponifiable portion, which we have chosen to call "congeneric oil," has been set to one side without any further treatment, except in a few instances, when it has been subjected to distillation. The acids are not true fatty acids, but are oxygenated acids, which are always aldehydic in character and respond to all the aldehyde reactions; and in fact their future industrial application may in some cases depend upon their

*A paper presented Dec. 9, 1921, at the Baltimore meeting of the American Institute of Chemical Engineers.

[1]Brit. Pat. 21,941 (1905).

aldehydic character. For example, if the saponification of the oxidation product of any petroleum fraction be carried out with caustic soda, so much resinification of these acids takes place that when the acids are liberated from the soaps by a mineral acid they appear as hard resin-like substances. In fact, it is not at all improbable that these resinified acids will find use as cheap varnish gum and paint film substitutes.

If the saponification be carried out with calcium hydroxide instead of caustic soda, insoluble lime soaps are obtained of good color, since this base has very slight resinifying action on the aldehyde acids. The problem of making soda soaps of good color from these acids must be solved, the writer believes, by first making the lime soaps, then the free acids and finally carrying out the soda saponification under conditions which do not permit resinification to take place.

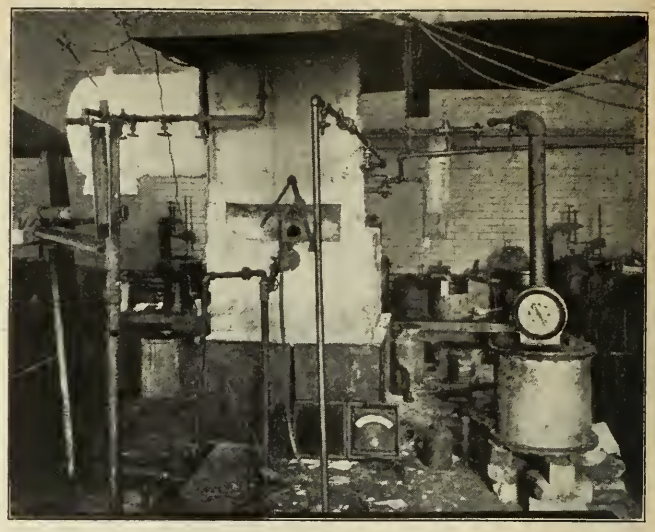
It is rather interesting to note that in the lime saponification it is very easy to make greases, the original components being lime soap, "congeneric oil" and water, and finally, if desired, only lime soap and congeneric oil. In fact there is always the problem of breaking up the grease, if it is desired to isolate the acids as noted above. It is believed that the best method for doing this is to remove the water by evaporation and then thin down the congeneric oil with one of the lighter petroleum fractions such as kerosene, filter off the lime soap and finally wash with a still lighter fraction, such as gasoline.

Development of New Fuel

Another phase of this work is the possibility of developing a new fuel from the cheaper fractions of petroleum by carrying out the oxidation at higher temperatures. These oxidized bodies thermally decompose to form both hydrocarbons or lower carbon content, and oxidized bodies of lower molecular weight. For example, with a fraction of Mexican fuel oil boiling from 300 to 360 deg. C. and running the oxidation process (by the three-screen method to be discussed later) so that the temperature is held between 380 and 400 deg. C. the liquid product obtained amounted to 80 per cent by volume of the oil treated. This product contained 30 per cent by volume of aldehydic fatty acids, 20 per cent by volume of other aldehydic bodies and the remaining 50 per cent consisted of other oxidized bodies and hydrocarbons. The latter were mostly of lower molecular weight than those of the original mixture, because of thermal decomposition of the oxygenated bodies. On distillation, 65 per cent of the product boiled under 300 deg. C. and of this fraction 18.4 per cent boiled below 200 deg. C. The oxygenated bodies are distributed through the entire range of fractions obtained by fractionally distilling the product, with more of the acids in the heavier fractions, and oxygenated bodies that have undergone thermal decomposition in the lighter fractions, along with hydrocarbons that have also been formed by thermal decomposition of the primary oxidation products. The distribution of the combined oxygen is shown by the following analyses made on a product obtained by the oxidation of a "pressure still tar," the residue from the "cracking" stills of one of the pressure cracking processes:

	Per Cent
Combined oxygen in fraction above 300 deg. C.....	4.1
Combined oxygen in fraction between 200 and 300 deg. C.	6.48
Combined oxygen in fraction under 200 deg. C.....	12.32

This fraction under 300 deg. C. might be called "oxidized" kerosene, and its properties certainly justify



VAPORIZER (RIGHT), CATALYST CHAMBERS (LEFT)

work in the direction of having it utilized industrially as a fuel in internal combustion engines. It may be used in kerosene engines, or blended with gasoline for use in gasoline engines. Although it has a somewhat lower fuel value than ordinary kerosene, owing to its oxygenated character, it undergoes much better combustion in the internal combustion engine.

A sample of "oxidized" kerosene made from Mexican gas oil, having a specific gravity at 15.5 deg. C. equal to 0.863, gave a calorific value of 18,210 B.t.u. per lb. A sample of Mexican kerosene that had been given a rather mild oxidation had a specific gravity at 15.5 deg. C. of 0.855 and gave a calorific value of 18,696 B.t.u. per lb. Three samples of ordinary kerosene from various sources gave for their calorific value in B.t.u. per lb. 19,827, 19,867 and 19,944, from which it would appear that the calorific value of these oxidized kerosenes is not seriously low.

The use of this oxidation mixture—such as is obtained from gas oil, for example—as a starting material in "cracking" processes has been studied to some extent. As far as these experiments have been carried, it is evident that low boiling mixtures, within the gasoline range, can be obtained by the thermal decomposition of this mixture. These experiments are, however, only in the laboratory stage.

Heavier Fractions Possess Lubricating Properties

The oxidation products obtained from the heavier fractions deserve attention from the standpoint of lubricant manufacture. Southcombe has recently brought forward the idea that a small percentage of free fatty acids added to a straight mineral oil lubricant would increase the lubricating character, particularly for those cases in which it has been necessary to use "blended" mineral and fatty oils. While this has been questioned, the writer ventures the opinion that at the present time the experimental evidence collected supports Southcombe.

The portion of the oxidation mixture that will be found suitable for use, either alone as a lubricant or as a blending agent, is the "congeneric oil" remaining after the acids have been removed. These high molecular weight oxidation products have valuable lubricating properties, a fact which appears to extend the Southcombe idea in another direction.

Although the idea is a daring one, the writer has suf-

ficient experimental evidence to make the claim that these oxidized oils will be found suitable for internal combustion engine lubrication. In this connection it should be remembered that the resinification property of these high molecular weight aldehydic bodies is brought out by treatment with the caustic alkalis. Under other conditions these bodies are really more stable than the fatty oils.

The sulphonation of the oxidation mixture has been carried out with a considerable degree of success. The acid portion sulphonates more readily than the other bodies present.

A promising application of the oxidation mixture in its entirety, just as it comes from the apparatus, is in the field of oil flotation. This mixture can serve primarily as a "frothing" oil in flotation mixtures, and numerous laboratory experiments have shown that it has, on the average, about one-half the frothing power of the best pine oil frother—that is, 2 gal. of this oxidized mixture will in general do the work of 1 gal. of the highest grade pine oil. When it is considered that this oxidized mixture can be made from fuel oil, available almost everywhere, and that pine oil f.o.b. New York costs $1.50 per gal., it would appear that this product may find use in the concentration of ores by oil flotation.

From experimental evidence it is the acid content of the oxidized mixture that gives this material its frothing character. However, for flotation work there would be no gain in separating the acids, as the congeneric substances dissolve readily in all oil mixtures. The frothing oil in flotation formulas is but a small percentage of the total oil, hence the congeneric oils do no harm, and being made from fuel oil, which is commonly used as a collecting oil, the whole proposition works out as a very economical means of getting fatty acids into flotation mixtures.

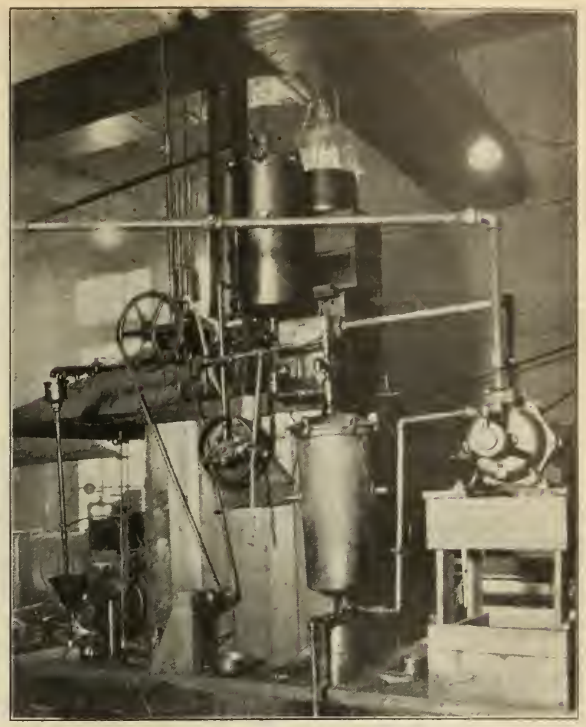
Developing the Apparatus

This process has been carried to what might be called the semi-industrial stage. In the laboratory of industrial chemistry at the Carnegie Institute of Technology there was set up a triple screen apparatus large enough to make about a barrel per day of the oxidized mixture from any petroleum fraction or blende that can be vaporized.

When the larger apparatus was first installed, one screen only of catalytic material was used, and the excess heat developed was carried off by a system of cooling pipes, the closed ends of which were imbedded in the catalyst.

Either air or water could be used as the cooling medium. In this oxidation of aliphatic hydrocarbons, the writer usually prefers to keep the temperature of the catalyst below 400 deg. C. (usually 280-380 deg. C.), hence in an apparatus larger than that used in the laboratory, the temperature tends to rise, because of the greater distance to any radiating surface and the nonconducting character of the catalyst and its carrier, which is usually asbestos.

The cooling tube apparatus worked fairly well, but later the double- and finally the triple-screen apparatus were developed. In the cooling tube system, one catalytic screen only was used, hence all the air that was to be introduced had to be given to the reaction at one time. With more than one catalytic screen, the air is introduced in portions before entering each screen, being distributed among the screens usually in equal amounts,



OIL FEED AND EXHAUST PUMP

but sometimes varying from this, if conditions demand it.

The triple-screen system also makes possible the use of different catalysts. It has been found that uranium oxide catalyzes the oxidation to the aldehyde stage, and at present uranium oxide is used for screen 1 and the molybdenum oxide mixture for screens 2 and 3.

The air is drawn into the system by a small pump, which in addition functions as a mechanical scrubber in aiding in the removal of the oil vapors from the gas stream. A parallel tube condenser placed about 15 ft. beyond the catalyzer (to allow for air cooling) is placed between the catalyzer and the pump.

Some Operating Data

The following example will serve to show the working of the apparatus:

Catalysts: three screens, all of molybdenum oxides, each 37.5 cm. in diameter and 1 cm. thick.

Oil used: Pennsylvania petroleum; a product sold at one time during the war as fuel oil by one of the Pittsburgh refineries: it showed the following on distillation:

First drop, 200 deg. C.	Per Cent by Vol.
200-250 deg. C.	11
250-300 deg. C.	51
300-350 deg. C.	34
Residue above 350 deg. C. and loss	4

Specific gravity of oil at 15.6 deg. C. was 0.819. Olefinic hydrocarbons (by the sulphuric acid test) was 7.5 per cent.

Time of run, 4 hours.

Average temperature of mixture leaving vaporizer, 310 deg. C.

Average temperature of first catalyst 335 deg. C.

Average temperature of second catalyst 370 deg. C.

Average temperature of third catalyst 370 deg. C.

Volume of air at room temperature and pressure passing into vaporizer and on into first catalyst, 70 liters per minute.

Volume of air added at second catalyst, 30 liters per minute.

Volume of air added before entering third catalyst, 30 liters per minute.

For the second half of the run, "fume" gas (50 liters per minute) was taken from exit line and added as diluent to lower the temperature at screen number two.

Rate of oil feed to vaporizer, approximately 6 liters per hour.

Rate of water feed to vaporizer, approximately 6 liters per hour.

Vacuum on system at vaporizer, 5 cm. of mercury.

Gas Analysis:

	Per Cent by Vol.
CO_2	2.9
O_2	2.9
C_nH_{2n}	2.5
CO	4.8
Undetermined (mostly N_2)	86.9

Volume of oil fed during run, 25.5 liters.

Volume of oily product (insoluble in water) recovered, 19.6 liters.

Specific gravity of product at 15.6 deg. C. was 0.86.

The product had approximately the following composition:

	Per Cent
Aldehydic fatty acids	31
Aldehydes (above 200 deg. C.)	20
Alcohols, volatile aldehydes and other oxidized bodies with hydrocarbons (by diff.)	49

The process works even better on oils having a lower market value than the Pennsylvania petroleum. For example, one of the easiest fractions to treat is what is commonly called "the gas oil fraction" from Mexican petroleum. The presence of sulphur compounds and of unsaturated hydrocarbons is no drawback to the application of the process, since the oils containing these bodies oxidize more readily. This therefore makes the process applicable to many refining wastes that now find their way into the fuel oil tank.

Patent applications covering the main process as well as its various ramifications have been filed in the United States and foreign countries.

Carnegie Institute of Technology,
Pittsburgh, Pa.

Atmospheric Nitrogen Production in Germany

The present extent of the production of nitrates in Germany by atmospheric fixation is discussed in *Commerce Reports* for Jan. 16, 1922.

Previous to the Oppau explosion in September, 1921, it was claimed that Germany was ready to supply, using the Haber-Bosch method alone, a combined production of 300,000 tons of nitrogen fertilizer, or enough with its other resources to take care of the most urgent needs of its agriculture. The aim of the industry, however, is to develop a production of 500,000 tons annually by this process alone, or sufficient to yield the maximum of vegetable produce from Germany's arable land, an amount estimated as adequate to feed a population of 100,000,000.

On account of the explosion, production ceased in the first plant in Germany to undertake the production of nitrogen by the Haber-Bosch process. The estimated output of this plant has been placed at 100,000 tons of nitrogen fertilizer per year.

Before the war Germany imported vast quantities of Chilean nitrates, together with various industrial by-products in the shape of nitrates of lime. In 1900 South America supplied Germany with 350,000 tons of nitrates; in 1909 with about 480,000 tons, containing 76,000 tons of pure nitrogen, valued at 95,000,000 gold marks. In 1913 German agriculture absorbed about 200,000 tons of nitrogen, sufficient to supply about 83 per cent of its population of 60,000,000 with cereals but insufficient to supply fodder for cattle.

Calcium-cyanamide factories in Germany have an output now of approximately 500,000 tons, with a nitrogen content of about 100,000 tons. Production of nitrogen fertilizers by the coke and gas industries before the war amounted to about 580,000 tons, with a nitrogen content of about 116,000 tons.

Corrosion Patterns on Cold-Worked Tin and Zinc

By Henry S. Rawdon, Alexander I. Krynitsky and Julius F. T. Berliner*

SPECIMENS of high-grade tin intended for pyrometric standards[1] were used in a brief study of the properties of tin after deep corrosion. The cross-section was reduced by cold-rolling from 2 by 4 cm. to a strip approximately 0.15 cm. thick, and the metal was then annealed for period of 2½ hours at 150 deg. C. Acidified solutions of stannous chloride were the corroding liquids used, alcoholic solutions rather than aqueous being employed on account of the influence of water in decomposing the salt. For reagents, a normal solution of stannous chloride to which hydrochloric acid was added to form solutions of the approximate concentrations 0.52*N*, 0.78*N*, 1.2*N* and 2.2*N* were used. The temperature was that of the room and varied between 12 and 30 deg. C.

The attack was distinctly more severe along the grain boundaries than in the interior of the grain. After a prolonged attack, it appeared that some of the grains had been detached bodily along the margin of the corroded specimen as is shown in Fig. 1. Corrosion was permitted to proceed for a period of 87 days and on sharply bending the corroded specimens, no evidence of intercrystalline fissures throughout the material was obtained except a suggestion of them in one case. In general, the metal appeared to retain its initial ductility

Some of the specimens of tin exhibited a very peculiar and striking pattern upon corrosion which was independent of and superimposed upon the granular or crystal structural pattern. This is shown in Fig. 2, and it appears to be related to the rolling that the material received. That it is not entirely a surface roughening caused by adherence of corrosion products or by convection or diffusion currents within the corroding liquid appears evident from the fact that very slight corrosion (1 hour) was sufficient to reveal it and also that it was still very prominent after 4 days' attack. The regularity of this cellular pattern is striking.

No explanation as to its meaning can be offered from the evidence in hand, though it can be stated that the properties of the tin after corrosion do not appear to be affected to any appreciable extent by this feature of the structure. The fact that the metal was annealed would indicate that the etch pattern cannot be attributed to the uneven removal of a relatively hard "skin" on the surface of the metal.

Zinc

The material used for experiment was a high-grade sheet[2] zinc furnished for the purpose by the New Jersey Zinc Co. The sheet was stated to be in the annealed condition when received; the microstructure indicated, however, that all the effects of the mechanical working had not been removed, so an additional annealing was given to some of the material. The small specimens, after being cut to size for the corrosion

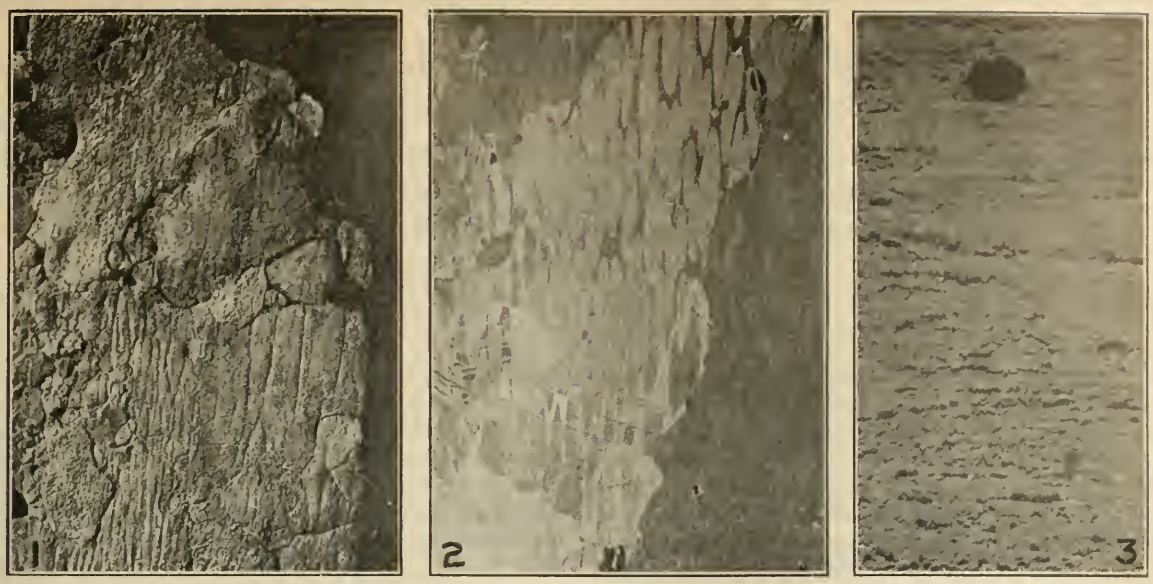
[1]The chemical analysis of the material indicated the following composition: lead, 0.007 per cent; copper, 0.003; iron, 0.002; a trace of each, arsenic and sulphur; antimony, not detected; tin (by difference), 99.998 per cent.

[2]The chemical analysis indicated the following composition: Lead, 0.04 per cent; Iron, 0.02; cadmium, trace; sulphur, not detected; zinc (by difference), 99.94 per cent.



FIGS. 1 TO 3

Fig. 1—Pure tin after 87 days' corrosion in N $SnCl_2$ + 2.2N HCl. × 5.
Fig. 2—Pure tin after 1 hour in N $SnCl_2$ + 0.6N HCl. × 5.
Fig. 3—Annealed zinc after 17 days' corrosion in N $ZnSO_4$ + 2N H_2SO_4; cleaned before photographing with 5 per cent acetic acid. × 2.

tests, were heated in an oil bath and maintained at a temperature of 350 deg. C. for a period of 3½ hours and allowed to cool in the oil, the entire period above 300 deg. C. being approximately 5 hours.

Normal aqueous solutions of zinc sulphate to which various amounts of sulphuric acid had been added in order to give a series of solutions of increasing acid concentration were used as the corroding liquids. The results obtained after a period of 17 days at room temperature are summarized in Table I.

TABLE I.—LOSS OF WEIGHT OF ZINC DURING CORROSION

Spec. No.	Dimensions, Cm.	Area, Sq.Cm.	Corroding Solution	Loss of Wt. After 17 Days,* G.	Loss per Sq.Cm. per Day, Mg.
1	4 x 2.1 x 0.12	17.26	N zinc sulphate	0.018†	0.06†
2	4 x 2.1 x 0.12	17.26	N zinc sulphate + N/4 sulphuric acid	0.157	0.53
3	4 x 2.1 x 0.12	17.26	N zinc sulphate + N/2 sulphuric acid	0.698	2.38
4	4.1 x 2.1 x 0.12	18.7	N zinc sulphate + N sulphuric acid	1.291	4.06
5	4 x 2.2 x 0.12	19.1	N zinc sulphate + 2N sulphuric acid	2.600	8.00

*The scale was removed from the corroded specimens by immersion in 4 per cent acetic acid solution before weighing.
†Slight gain caused by incomplete removal of the corrosion scale.

The attack of the metal appears to be, at least in part, intercrystalline in nature, as is best shown by examination of the edges of the corroded sheets and the margins of corrosion pits. However, upon sharply bending the sheets after corrosion no pronounced evidence was obtained which would indicate that the metal had been embrittled or otherwise seriously affected in its properties as is the case with lead after corrosion under similar conditions.

The character of the corroded surface appears to have been determined in a very large measure by the mechanical working which the material previously received. The pits resulting from the corrosive attack were arranged in rather definite lines which coincided with the direction of rolling of the sheet. This feature was noticeable even in the annealed sheet, but more so in the commercially annealed metal. Fig. 3 shows an annealed specimen after corrosion for 17 days in N $ZnSO_4$ plus 2N H_2SO_4. Results obtained by prolonged corrosion in solutions of zinc chloride and of zinc nitrate with additions of the corresponding acid were very similar to those described above.

Upon sharply bending the specimens after the prolonged corrosive attack no satisfactory evidence was obtained which would warrant the conclusion that the metal had been seriously affected in an intercrystalline manner.

The Metallurgical Situation in France

According to figures reproduced in the French press, the total production of iron in France in 1921 was 2,074,732 tons, as compared with 3,265,000 tons in 1920 and 5,207,197 tons in 1913. The steel production for 1921 is given as 2,602,800 tons, as compared with 2,914,800 tons in 1920 and 4,686,866 tons in 1913. Thus the reduced activity in France is not as considerable as in Belgium, where the 1921 production of iron was only 34.7 per cent of the 1913 figure. The only country where production has increased is Germany, where, according to the same estimates, the production of iron rose from 7,000,000 tons in 1920 to 8,000,000 tons in 1921 and that of steel from 8,400,000 in 1920 to 9,400,000 tons in 1921.

A steady improvement is noticeable in the metallurgical industries in the Lyons district. The orders given by railway companies for locomotives and rolling stock and for repair materials have recently been so numerous that certain works are short of skilled hands. An improvement is remarked in the construction of machines for the cardboard and paper industries, and one establishment, which specializes in the construction of installations for slaughter houses and refrigerating warehouses, is seeking skilled hands.

Metallurgical works are profiting by the resumed activity of the chemical industries, which are ordering new vats and reservoirs, but the situation in the boiler trade is regarded as serious. Cast iron and steel foundries are receiving a certain number of orders, and although fewer workers are employed than in a normal period, work is active. Copper foundries are also more active, the tap industry having improved considerably.

Breakage Factors in Silica Brick Manufacture

A Critical Discussion of Those Factors in the Manufacture of Silica Brick Which Determine the Breakage Records—Properties of Silica Rock—Grinding—Effect of Bats—Workmanship—Drying—Setting in the Kiln—Burning—Methods of Firing

By PHILIP H. JUNG
Consulting Chemical and Metallurgical Engineer

OF ALL refractories, silica brick are probably the most difficult to manufacture, or in other words, it is most difficult to obtain a low breakage record on silica brick. The reasons for this are, first, that the very nature of silica, considered from its physical aspects, makes it difficult to bond and shape as compared to an argillaceous substance, and second, that extreme care is required in burning and cooling, as silica will not stand rapid changes in temperature. Users of silica brick sometimes do not take this into consideration, and, in these cases, when brick are subjected to rapid heating and cooling, they soon fail and are condemned unjustly. At the present time manufacturers are interesting themselves in a silica brick machine and find that more intricate problems have to be faced than in the case of fireclay.

Breakage is a matter of uniformity, and the various factors that influence breakage are being more clearly recognized than heretofore. Investigations are continually being carried on to determine correct practice and then an effort is made to adhere to this.

Properties Desired in the Silica Rock

First of all, we have the character of the rock to consider. The physical appearance of silica rock or ganister varies considerably. Some of it is dark, some light, some streaked and the surface of some highly discolored. Of course, the purest rock is white. A colored rock is not necessarily one to be rejected. Very often a very high-grade rock is highly colored on the surface and gray throughout the mass. In the same quarry, the floe or surface rock will almost always vary from the solid measure rock. Some quarries will give an excellent floe rock and others a superior solid measure rock. Manufacturers differ in opinion as to which is the better. A clean-looking rock usually implies a pure rock, which forms a crude index of the chemical analysis. However, the physical features of the stone equal and perhaps exceed the chemical composition in importance. Sandstone which shows a very high percentage of silica is unsatisfactory for making brick, because it lacks physical strength. It invariably consists of rounded grains that are not tightly cemented to one another. On the other hand, there is a mountain of rock in the state of Washington which is pure quartz and translucent in appearance. It is entirely of a crystalline structure, and on fracture will break into small fragments with edges as sharp as a needle. Experiments have shown that a rock which is too pure, or in other words lacking some alumina and iron to aid in bonding, is difficult to bond even with a large percentage of lime, and this is especially true when the structure is all crystalline. Therefore the best rock for making silica brick is one not too pure (under 99 per cent silica) and one which consists of crystals, which break into sharp fragments and which are cemented together with a ground mass of granular quartz. In this case the amorphous quartz, alumina and iron will aid in the bonding and help to make a physically stronger brick, other things being equal. Furthermore, such a rock will be difficult to pulverize. It is evident, then, that the selection of rock is of prime importance and that an experienced quarryman is absolutely essential.

After the rock has been crushed to the desired size, it is conveyed into bins, from which it is fed into pans having double mullers, milk of lime being added, and this mixture is ground and mixed thoroughly and constitutes what is known as silica mud. Sometimes bats are ground with it. What bats are and how they affect the situation will be discussed later on. The lime, if kept within certain limits, does not affect the breakage as much as was once thought. To be sure, it is an important factor and needs constant watching, but it cannot prevent a high breakage if other important factors are not uniform.

Importance of Uniform Grinding

It has been mentioned above that the rock is ground to a desired fineness. How fine or how coarse this must be depends on circumstances. A coarse grind means more abrasive qualities, ability to stand greater wear and tear and greater porosity. A fine grind means better filling out of corners, denser brick and greater thermal conductivity. As a rule, brick for open-hearth furnaces are coarsely ground and brick for byproduct coke ovens and glass tanks are ground finer. It is quite difficult to get a uniform grind. Experiments have been made often, the utmost care being taken to have the same rock as near as possible, the pans being properly repaired and time identical, and yet divergent results have been obtained. My personal view is that the varying factor lies in the hardness of the rock. No doubt practical brick manufacturers will dispute this point and maintain that their rock does not vary enough in hardness to warrant this inconsistency in grind. However, although no series have been made conducted along this line to my knowledge—that is, to show the exact relation between variation in grind and hardness of rock—my belief is that a small variation in the hardness of the rock will cause a much greater variation in grind than is thought possible. At least personal observation and practical experience lead me to believe this. All told, grind is an important factor, and whereas it does not influence breakage as heavily as some other factors, it does have a tendency to affect workmanship, which will be discussed later.

The next thing to consider is the amount of water to add in the brick mud to make it plastic and workable. Moisture varies ordinarily from 7 to 13 per cent. Below and above these limits it is quite noticeable. Below 7 per cent the mud feels very dry to the touch and above 13 the excess can easily be squeezed out and is so apparent that brick with that amount of moisture that have just been molded and set aside to temper sag at the edges and the excess water appears in beads on the surface of the brick. When carefully watched, it is very easy for an experienced pan-runner to get between 10½ and 12 per cent day in and day out. It is remarkable how accurate the workmen become with practice, simply by feeling before dumping the mud on the table. When it is a trifle wet, say 12 per cent, it will help toward making a firmer bond than if it is a little drier. Strength tests have shown this. The moisture is not difficult to control and therefore does not cut much figure in the breakage item. Furthermore, molders refuse to work with mud that is too wet or too dry, especially if the brick are branded with the molder's individual brand, and therefore it is very seldom that brick enter the driers having this defect.

Along with the question of moisture and closely allied to it is that of introducing scrap. By this is meant the addition of dry mud obtained from rejected green brick in order to give the charge the right plasticity, or in other words, when too wet, to correct this fault. Inasmuch as so little is added to the ordinary charge, and then only at intervals, it has practically no bearing on the breakage.

Effect of Bats on Breakage

A statement has been made previously concerning bats and their effect on breakage. The term bats applies to rejected burned brick which are used over again in preparing the brick mud mixture. I doubt whether there is any subject concerning the manufacture of silica brick about which there is so much controversy and which arouses so much ire. Up to the present time it has not yet been shown just what amount of bats is correct, if any. The consensus seems to be around 15 per cent. At the present time I know of three silica brick yards that differ on this question. For example, yard 1 issues instructions to its pan-runners to add so many 9-in. brick (6 lb. apiece) to each charge and attempts to adhere to this religiously. In this case the amount happens to be about 8 per cent. Yard 2 never adds any unless the breakage is unusually high, and then only to get rid of the excess and in small quantities in each charge. Yard 3, after some technical investigation in the matter, came to the conclusion that the effect on the strength of the brick was not very great, that is, up to a certain point. For a time bats were added indiscriminately in spite of the fact that the mixture was hard to work with and was detrimental to small breakage records, because rigid inspection has shown that a high percentage of bats does not give the brick the clear ring when tapped with a hammer. But later on this practice was discontinued.

Just how does the addition of bats affect the structure of the brick? It is quite evident that if two brick receive an equal degree of burn, one containing no bats and the other about 20 per cent, the first will have expanded further than the other, because the latter contained 20 per cent of material that had already been burned and expanded. The natural inference would be if one part of the brick expands more than the other part, this might cause fissures and even a rupture of the brick. However, strength tests have not borne this out. In fact a small percentage of bats seems to make a little stronger brick, especially when added in a pulverized form. Moreover when being molded, it is unquestionably more difficult to bond a small piece of bat to a piece of raw rock than it is to bond a small piece with another. This, however, is self-corrective, inasmuch as in burning, when changing from free lime to tricalcium silicate, the chemical change is the same in either case, at least there would be the same knitting together, although, as noted above, it would seem physically as if fissures would appear. The question as a whole is as yet difficult of solution, but it is conceded at least that it affects breakage considerably, if only from a standpoint of rigid inspection.

Workmanship

We now consider the important item of workmanship. This and burning probably affect breakage more than any other two factors.

It is a curious fact that according to the popular mind, the only big requirement for a brick is to shape up well, or in other words to fill out the mold exactly, with edges sharp. This conception is due no doubt to the fact that the average person invariably thinks of a building brick, which of course must be straight, so that it can be laid right. When considering refactory brick, however, although workmanship is not everything, yet it is a great deal. In the first place, the molds are very carefully made, and the process of molding varies with the kind of brick being made. When ordinary 9-in. straight are being made, slop mud is used—that is, two handfuls are thrown in the mold simultaneously and with considerable force, the hands being about 6 in. above the mold. The impact is sufficient to fill the mold completely. It is then slicked off and the brick pressed out. In case of shapes, especially where the shape is large and intricate, the brick are more carefully made. The mud for this purpose is both finer and more dry, as noted before. The edges of the mold are filled in first and the mold partly filled with mud and then hammered. This is then stirred around to prevent cleavage and enough mud added to fill the entire mold, which is then slicked off as in the previous case. The molds are so made that they can be taken apart, thus freeing the brick easily. A brick that is not carefully filled out is usually spongy in appearance. Sometimes brick warp and are not exactly straight. This may be due to poor workmanship or else the use of mud that was too wet. However, brick sometimes warp in spite of every precaution. Workmanship is such an important factor in this department that rigid inspection is essential, and this, together with the fact that physical imperfections can be seen, ordinarily reduces to a minimum the breakage for which this department is directly responsible.

Drying an Important Factor

After the brick are made, they are put on a rack-car and left standing in the open air to temper properly. This process permits the brick to dry very slowly and harden, an action not unlike the setting of cement. Special shapes are put on a hot floor and permitted

to remain there sometimes several days. After they are tempered, they are put in the driers. Temperature uniformity is of prime importance in drying and is difficult to obtain, owing to the fact that the old-time method of employing waste heat from the kilns is still utilized in brick plants, both because of economical operation and for want of something better to meet the situation. The hot air is drawn in by huge fans and the temperature is controlled by opening and shutting blades on the fan. Even then unless the temperature recorders are closely watched, there will be considerable temperature fluctuation. The incoming end of the drier must be comparatively cold compared to the outgoing end.

As the brick are placed in the drier, they gradually work their way forward, being pushed by others behind them and in this way they reach the hottest zone, which should be just before reaching the outgoing end. This sometimes is as high as 325 deg. F. The reason for this is that if they are suddenly plunged into a temperature of 300 deg. F. or over from ordinary temperature, the sudden formation of steam will cause cracks in the structure and the bond will be somewhat broken. In other words, shattering on a small scale is the result, and, although the same thing occurs on a much larger scale in rapid burning, the damage is just as severe, and it leaves the brick while yet in the green state in a friable condition and with a cracked sound when tapped with an inspector's hammer. Time and time again, brick that were apparently O.K. in other respects were in this condition and were set and burned. This not only represented a waste of time and money, but was misleading in investigating the cause of high breakages. I recall a startling example of a case where a sudden depression in the industry proved to be a blessing in disguise, because the management, having more time to investigate such matters because of diminishing orders, finally found a clew to what had caused them grave concern for months. After investigating every possible source of trouble, they found that fully 10 per cent of their breakage was due to rapid heating and lack of temperature control in the driers.

Owing to practical condition, at times some time elapses after the brick are taken out of the drier and are set. A series of experiments run to establish a relation between absorption of moisture by green brick and the weather conditions proved that in no case was sufficient moisture absorbed to give concern, and furthermore, even on long standing, the amount of moisture absorbed was negligible. Whereas this is but a minor matter in the manufacture of silica brick it proved that if any appreciable moisture was present, it came from improper drying and thus an alibi long used by the drying foremen was no longer available.

Setting the Brick in the Kiln

Although the setting has a great deal to do with breakage, it should not occupy a prominent place in a technical dissertation of this kind. Proper setting is a matter of skill backed by years of experience in the brick industry. In the first place, it should be noted that the kiln has been properly repaired, that the fireboxes are in good condition, the riddle holes well cleaned out and the kiln-floor as nearly level as possible. All this helps both in setting and burning. In down-draft kilns, such as are being used in the silica brick industry, checkerworks of old brick are built in back of each firebox to divert the path of the flame upward toward the top and middle of the kiln, whence it is drawn down through the riddle holes and up the stack. Another reason for the erection of checkerwork is to prevent fire-flashing of ware nearest the firebox. The order or style of setting depends on the kind of shape being set. Ordinarily, difficult shapes are boxed in—that is, surrounded by benches of 9-in. or other small straight brick.

There usually is a preponderance of standard easy makes, such as 9-in., wedge, large 9-in., soaps, feather-edge, etc. These are usually nearest the fireboxes. The usual procedure of setting is to start with a course of tie-brick—that is, brick that have been burned over and over again and are used to support the courses of green brick that are being set. Several courses or rows of brick are set on top of this and then another row of the tie-brick. Sometimes brick are set on edge, either lengthwise or breadthwise, but in any case it is necessary to alternate this procedure with each row. This permits proper spacing between brick, which is important, as brick must have room to expand. After the setting is completed, a space is allowed for test brick and testing cones, the doors are sealed and coal in the fireboxes ignited with oil, pitch or other flammable material.

Burning a Major Factor in Breakage

We now come to the burning. This and the workmanship form the two major operations in silica brick making and ordinarily influence the breakage more than any other factor. Attention has been called to the fact that silica brick are difficult to make and that one of the principal reasons for this is found in the structure of silica. This becomes very evident when the subject of burning is considered. A silica brick must be heated slowly and cooled slowly. Rapid heating causes spalling or chipping off into slivers and even disintegration. Even when heating moderately fast the brick are apt to swell, causing excessive expansion, and sound brick do not result. Likewise rapid cooling causes fine cracks and slight disintegration. A fundamental fact is that a silica brick does not expand uniformly. Half of the expansion occurs below 600 deg. C. and the brick are burned to 1,500 deg. C. In speaking of expansion, it is well to remember that there are two kinds of expansion. The first or permanent expansion is that which occurs when a brick changes from the green state to a burned state, or technically speaking from quartz to crystobalite tridymite. In a well-burned brick this should be between $\frac{1}{4}$ and $\frac{3}{8}$ in. per linear foot. The other expansion is a temporary one which occurs when any substance is heated (except of course those substances that shrink on burning), and this expansion disappears on cooling. A well-burned brick does not mean one which has been burned to its extreme expansion limit, since it can be overburned as well as underburned. On the contrary, a very slight difference between the utmost expansion and actual expansion should remain, as this will help the brick fit tightly together when used in the open-hearth furnace or coke oven. This slight difference should be known and provided for. A well-burned brick will ordinarily have a clear ring, will measure up to standard if the amount of bats are not excessive, and will have a specific gravity under 2.36. The term specific gravity here refers to the true density of the

brick, irrespective of the porosity. The bulk density takes the brick as a mass and allows for the porosity. The figure varies according to physical structure of the rock used and its geographical location. Eastern rock burns to a lower density than Western rock.

In burning brick made for byproduct coke ovens, the shape and size of the brick are important considerations. The shapes are very often large and thick and sometimes intricate. It is therefore more difficult to burn these thoroughly than ordinary run of kiln. Such being the case, it quite frequently happens that a brick is burned so hard as to be called overburned. An overburned brick is just as apt to cause a high breakage as an underburned one. It is practically burned to its expansion limit in the first burn, or, in other words, a second heating and burning when used by the consumer in his ovens will bring about only a minute residual expansion, sometimes insufficient to knit the brick together. But the worst feature, from the manufacturer's standpoint, is that in overburning, minute fissures appear, which give the brick a cracked sound, causing a rejection. Furthermore, from an operating cost standpoint, it takes lots of coal to bring about an overburned condition. The consumer's specifications in this connection are now so rigid that the manufacturer in trying to give him a well-burned brick is apt to get a run of overburned brick. However, in most cases, he has met this admirably and the quality of coke-oven brick is constantly improving. An underburned brick, in the first place, has not the physical strength and from a consumer's standpoint is highly undesirable, as it will expand excessively when used causing tilting and failure of walls in the coke-oven.

Heavy Firing vs. Light Firing

Heavy or light firing is another point where manufacturers differ. In "heavy" firing, a lot of coal is put into the firebox at one time and at long intervals. During these intervals the coal is gradually burned to incandescence, causing a long flame which is necessary to burn silica brick. This argument is used by the advocates of this system. But the disadvantage is that when the next firing time is due, an addition of a lot of fresh coal causes a sudden decrease in temperature. The effects of this are self-evident. In light firing the coal is added in smaller quantities and at more frequent intervals, thus bringing about a greater uniformity of temperature. The disadvantage is of course that the fire is mostly in the coking stage and combustion takes place nearer the firebox because of a smaller flame and in this way it is more difficult to burn completely the brick that are farthest away from the firebox. The determining factor in the method adopted depends upon the character of the fuel available.

Control of the Burning Operation

In the question of burning control, several aids are used. The temperature is gaged by the pyrometric cones, but unfortunately they show only when the burn is completed—that is, fusing at the final temperature desired. It has been noted before that silica brick expand unevenly and the cones give no indication of what is happening during successive temperature changes. The use of pyrometers has been suggested to overcome this difficulty. They have not been successful in the silica brick industry and to my mind have been unjustly condemned in some cases, due to the fact that they indicate the temperature at only one spot in the kiln and to the inaccuracy in recording the higher temperatures. This is no reflection on the merits of the pyrometer, as numerous papers have been written showing their successful application to many industries. This paper attempts only to record the actual experience of the pyrometer in the silica brick industry. The writer sees no reason why the pyrometer could not be used here in the future, even if only during the critical period, when most of the expansion takes place.

The other aid to proper burning is the draft gage. A uniform draft, like a uniform temperature, is desirable. Some works prefer the draft gage as a means of controlling temperature, but its use is open to discussion. Experienced users state that 0.4-in. is ideal but difficult to attain. Of course, the actual draft varies with the kind of fuel employed and also with the location of the gage.

Only experienced firemen should be employed, the test brick watched, and the appearance of the flame noted through the peep-holes. Old hands become very accurate in telling temperatures by this means. The cooling is the reverse of burning. Less and less coal is used until finally the fireboxes are sealed and then the air is gradually let in. The door is then taken down. Fans are sometimes placed at the fireboxes to assist in cooling. The time of firing usually takes from 5 to 8 days depending upon the kiln and cooling takes the same amount of time.

This practically covers the whole subject of breakage factors. Sometimes careless handling in taking brick from the kiln to the stockshed or cars increases breakage, the percentage from this source usually being very small. This, of course, requires the vigilance of the foreman of this department.

Huntingdon, Pa.

Mineral Production of Spain

A report recently published by the Ministry of Fomento ranks Spain as the second country in the world in the production of copper, the United States being first, according to an article appearing in the Jan. 23, 1922, issue of *Commerce Reports*. Ninety per cent of the Spanish production of this mineral is controlled by British interests, and most of it comes from the Rio Tinto mines, which are developed by foreign capital. In 1919 there were exploited 622 hectares of mineral copper, which produced 864,414 tons, valued at 13,387,261 pesetas at the mine.

Spain is second in the production of lead, according to the same study, and in 1919 produced 136,180 tons of lead ore, valued at 46,129,647 pesetas, and 41,875 tons of silver-bearing lead, valued at 10,259,351 pesetas. French capital controls the Penarroya lead industry.

In production of mercury Spain leads all countries, having produced in 1919 24,966 tons, valued at 6,356,435 pesetas at the mine mouth. This represents an exploitation of 196,554 hectares. All of the quicksilver is exported under contract with the Rothschilds. Production of nickel, chromium and similar minerals is insignificant.

Although most of the Spanish industries converting raw metals into finished products are very small, there are eight enterprises employing over 1,000 men and thirteen others employ over 500 men.

The Determination of Nitrogen in Steel

An Extended Review of the Literature Covering Past Attempts to Determine Nitrogen in Steel Is Followed by a Detailed Description of the Reagents and Apparatus Recommended for the Determination of Nitride Nitrogen

By FREDRIK HURUM and HENRY FAY

ALTHOUGH the presence of nitrogen in iron and steel has been an established fact for almost a century, it is surprising to find what a small amount of definite and reliable information is available on this subject. The reason why so little is known about nitrogen in steel is undoubtedly due to the difficulty of analyzing for this element.

The value and outcome of any investigation on the effect of nitrogen on steel depend on a reliable and practicable method of analyzing for nitrogen, and the writers endeavored to work out such a method and try out its merits.

The method as worked out and which proved to be very successful is described herein, together with a discussion of the bibliography bearing upon the subject.

Historical Notes on Analysis of Nitrogen in Steel

The first mention of any compound between iron and nitrogen was made by Berthollet[1] and Thenard, who permitted ammonia gas to act on iron wire at red heat and found that the weight of the iron scarcely increased but that the metal became brittle. The discovery of nitrogen in commercial iron and steel appears to be due to Schafhäutl,[2] who during his stay in England in 1839 pointed out that both white cast iron and the English cast steel contained nitrogen besides carbon, and he claimed to have determined this amount quantitatively. To determine the nitrogen in large steel samples, he used the Dumas method, burning the iron in vacuum with copper oxide and measuring the liberated volume of nitrogen. For small samples he heated the sample with caustic alkali and caustic baryta. Ammonia was formed, and this was absorbed by hydrochloric acid and determined as ammonium platinum chloride. Schafhäutl found results running between 0.2 and 1.2 per cent nitrogen.

In 1850 Marchand[3] published the results of his experiments on heating steel with metallic potassium, endeavoring to obtain all the nitrogen in the steel together with some of the carbon as potassium cyanide. Marchand points out that it is very likely that ammonia and cyanogen are carrying nitrogen into the steel, both in the blast furnace and during case-hardening operations. In the blast furnace he attributes the result to ammonia in the fuel, and the formation of cyanides from alkali metals in the flux. When discussing the cementation process he says it is a well-known fact that animal charcoal is particularly effective in transferring iron into steel. He believes that iron and steel are likely to contain nitrogen as a nitrogen-carbon compound, and mentions cyanogen and paracyanogen as likely.

Marchand recommends analyzing for nitrogen in steel by the same method which Lassaigne has proposed to use for every carbonaceous substance which contains nitrogen—viz., heating with potassium or sodium and determining the potassium cyanide. He heated the powdered iron samples strongly with metallic potassium in a glass test-tube and excluded the nitrogen of the atmosphere by conducting a current of hydrogen into the test-tube through a two-hole stopper. He never succeeded in finding nitrogen in steel whenever precautions were taken to exclude the atmospheric nitrogen. Marchand was, however, able to detect nitrogen when using Schafhäutl's method. In cast iron he found 0.03 per cent nitrogen, which was one-twentieth of the amount found by Schafhäutl. The results, however, he admits are very doubtful and concludes that the nitrogen does not exceed the amount of 0.02 per cent.

Buchner[4] claimed that he was able to detect sulphocyanides in iron from Tyrol. This iron left when dissolved in hydrochloric acid a carbonaceous residue. He mixed 240 g. of this residue with potassium carbonate, this latter substance being entirely free from sulphates, cyanides and chlorides. The mixture was heated strongly in a small retort over a coal fire for 1½ hours.

The alkali in the fused mass was separated from the iron by extraction with water, and this colorless solution gave a blood red color with ferric chloride. This also happened with acid iron sulphate, but in neither case in alkaline solution. Buchner has excluded atmospheric nitrogen by submerging the neck of the retort in hydrochloric acid. He does not mention, however, the probability of exposing the retort to sulphurous and nitrous gases from the coal fire.

Buchner pointed out that a small amount of ammonia was absorbed by the hydrochloric acid, but the reaction with platinum chloride was not strong enough to warrant any quantitative determination.

In 1861 Fremy[5] tried to determine the nitrogen by heating samples in a current of hydrogen and measuring the decrease in weight, assuming that all the nitrogen would be given off as ammonia. He claimed to have found considerable amounts of nitrogen in all his iron samples. Bouis[6] refined the method of Fremy and found very much lower results, not over 0.18 per cent.

No positive results seem, however, to have been obtained until Boussignault[7] in 1861 developed a method which today is used as the basis for nitrogen analysis. He dissolved the steel sample in dilute hydrochloric

acid and obtained the nitrogen as ammonium chloride. He then distilled this solution over lime, and titrated the ammonia in the distillate with sulphuric acid. Boussignault found only very small amounts of nitrogen in steel.

F. C. Calvert[8] made experiments on the solution of cast iron in acids. He found that dies of cast iron about 1 cm. square would dissolve slowly in acids without appreciably changing volume, but left a well-defined structure of carbonaceous matter high in iron and richer in nitrogen than the original. His experiments extended over long periods of time. He found that acetic acid would attack cast iron slowly but steadily for years without necessitating a renewal of acid. Other acids, however, dissolved the iron more rapidly, but would have to be renewed from time to time.

Boussignault's method was reviewed and criticised by Ullgren,[9] who demonstrated that by dissolving 10 g. pig iron in concentrated hydrochloric acid, part of the evolved ammonia would pass over with the hydrocarbon gases, even when not applying heat, and this amount of ammonia could be determined by conducting the evolved gases through hydrochloric acid solution free from ammonia. By distilling this acid solution with excess of caustic lime, he could, when titrating the distillate with oxalic acid, find up to 0.2 mg. ammonia that otherwise would not have been accounted for when using, for instance, Boussignault's original method. He was further able to show that the amount of ammonia carried off with the evolved gases when dissolving steel samples in hydrochloric acid solution increased when a stronger concentration of hydrochloric acid was used. He then suggested using neutral cupric chloride solution for dissolving the steel sample and found in a sample of 2 g. gray pig iron 0.103 per cent nitrogen. Ullgren found that the steels would contain from 0.1 to 0.7 per cent nitrogen.

Rammelsberg,[10] who used a similar method, found only 0.002 per cent nitrogen. In 1865 Rinman[11] published in Stockholm the results of his work. He found only very small amounts of nitrogen in steel (0.005 to 0.016 per cent). After the proposal of Ullgren he also attempted to prevent the evolved hydrocarbon gases from carrying off any ammonia when dissolving the sample. He distilled the solution as usual and titrated the ammonia in the distillate with oxalic acid.

No Reaction Between Iron and Nitrogen

Stahlschmidt[12] in his paper "Beiträge zur Kenntnis des Stickstoffeisens" reported the formation of iron nitride containing 10.8 to 11.4 per cent nitrogen, when using Fremy's method of heating ferrous chloride with ammonia below red heat. This compound would correspond to the formula Fe_2N. He attributed the difference in the value of 0.6 per cent nitrogen to incomplete reaction or formation of ammonium iron chlorides not easily vaporized. Stahlschmidt was not able to find any reaction at all between free nitrogen and pure iron, even when using freshly reduced spongy iron. He was able to show that free nitrogen would not combine with iron even in the nascent state. In this latter experiment he heated iron oxide in a mixture of nitrogen and hydrogen. The water formed from this reaction was free from ammonia and the iron free from nitrogen.

Stahlschmidt further reported that iron nitride, when brought to a red heat in contact with steam, decomposed with formation of iron oxide and ammonia. He also showed that hydrochloric, sulphuric and nitric acids would dissolve nitride rapidly with formation of ammonia salts. He reported that iron nitride was not attacked at normal temperature by the halogens, but was attacked at an elevated temperature. The specific gravity of iron nitride he found to be 6.03.

At about the same time Stuart and Baker[13] attempted the analysis of nitrogen in steel, but in most cases could not detect any. They used Fremy's method and took every precaution of purifying and drying the hydrogen gas.

Allen's Researches

Allen[14] in 1880 tried to determine the nitrogen in steel by means of steam which he passed over the red-hot sample, making use of Stahlschmidt's previous observation. The iron nitride was decomposed, giving ammonia and iron oxide, and the ammonia was collected in the condensed vapor and determined. Allen did not get any reliable results with this method. Afterward he had better success with Boussignault's method, using Nessler's reagent to determine the ammonia in the distillate. He distilled the solution over lime. Allen's colorimetric method was adopted and used later to a great extent for the determination of nitrogen in steel.

Harbord and Twynam[15] used Allen's method without any modifications in their researches, and found that steels examined by them would contain from 0.000 to 0.024 per cent nitrogen. Langley[16] in his results used Allen's colorimetric method, with the modification that he substituted sodium hydroxide for calcium hydroxide, and he also attempted to purify this alkaline solution by destroying any nitrites and nitrates by means of a copper-zinc couple.

Tholander[17] dissolved the steel sample in dilute sulphuric acid and distilled over sodium hydroxide solution. He used the iodide-iodate method to determine the ammonia in the distillate. This method seemed to work out very nicely. Braune[18] published in 1906 the results of his extensive work on nitrogen in steel, a work which covered several years and aimed to render a complete account of the subject. Braune used the colorimetric method based on Nessler's reagent, and analyzed a great variety of steel samples.

Braune suggested using 1 g. sample for 0.03 to 0.005 per cent nitrogen in the steel sample and smaller samples for higher contents. For dissolving 1 g. of steel he used 20 c.c. hydrochloric acid of sp.gr. 1.124. He filtered this ferrous solution and distilled it over 20 c.c. potassium hydroxide (equivalent to 20 c.c. hydrochloric acid sp.gr. 1.124). Braune then determined the amount of ammonia in the distillate with Nessler's reagent. He recommends taking 2 c.c. standard Nessler's reagent and diluting to 10 c.c. He then adds the whole at once to the distillate and stirs. The

solution is then diluted to 150 c.c. In a special sample tube the color of this solution is matched to the color of a standard solution. This standard solution is prepared by dissolving 0.038147 g. ammonium chloride in 1 liter (i.e., 1 c.c. to 0.01 mg. N_2). He now takes 3 c.c. of this standard solution, treats it with Nessler's reagent and dilutes it to the same color intensity as the distillate. From the volumes used the nitrogen content is then computed.

Braune made tests and confirmed Stahlschmidt's assertion that all the nitrogen in a soft steel (0.06 per cent C) would be present as ammonium salt after dissolving the sample in hydrochloric or sulphuric acid. Braune also extended his researches to determine whether or not nitrogen might be present in the insoluble matter (graphite and temper carbon) left when dissolving a steel sample in acid.

He was not able to find any nitrogen in this residue and came to the conclusion that contradictory results by previous experimenters were likely to be due either to inexactness of method or to the ease with which this residue would absorb nitrogen from the atmosphere. Braune, however, admits the possibility of secondary reactions resulting in precipitation of a black matter from the acid with the carbon in the steel, evidently an organic compound of ammonia. Braune points out that in the color carbon test it is not the nitrogen from the steel but the nitrogen from the nitric acid that takes part in the reaction and results in the organic compound rendering the brownish color.

Method of Grabe and Petren

Grabe and Petren[19] made a thorough investigation on the methods of analysis of nitrogen in iron and steel. They used the method involving the use of potassium iodide and potassium iodate in the presence of dilute acid and made comparisons of this method with the colorimetric method as used by Braune. Grabe and Petren followed the ordinary procedure of dissolving the steel sample in acid and distilling this solution with an excess of alkaline solution. They collected the distillate containing the ammonia in 5 c.c. N/20 sulphuric acid so as to insure complete absorption of the ammonia as ammonium sulphate. They then titrated the iodine set free by the excess acid with sodium thiosulphate after having added potassium iodide and potassium iodate. They came to the conclusion that the colorimetric method was by no means exact enough and found that results obtained by Braune would disagree widely with results obtained with the iodide-iodate method. They showed that traces of nitrites in the alkalis used for distilling would to a great extent effect the results, and in some cases the nitrogen from this source would exceed the amount of nitrogen in the steel sample. However, they believed that hydrocarbon compounds (18 to 20 per cent of which may remain in the ferrous solution) would interfere with the iodine titration. They held the belief that unsaturated hydrocarbon compounds of the olefin series might combine with the iodine.

Tschischewski[20] asserts that the iodate method will give higher results than the colorimetric method of Nessler. He attributes this to the formation of amines, which are formed when dissolving the steel and which have a much lower coloring effect than ammonium chloride toward Nessler's reagent. Tschischewski suggested using a 6-g. steel sample and dissolving in 35 c.c. hydrochloric acid of sp.gr. 1.19 and adding 50 c.c. pure water. He distilled his ferrous solution with 40 c.c. potassium hydroxide (1:1) to 50 c.c. water. The distillate was collected in 20 c.c. N/100 sulphuric acid.

W. Herwig[21] determined nitrogen in iron and steel and used for his analysis a 5-g. sample which he dissolved in 50 c.c. hydrochloric acid of sp.gr. 1.124 and to which he added 40 c.c. water. On distilling this solution he prescribed addition of potassium hydroxide until the solution became only slightly alkaline. The distillate was collected in 20 c.c. N/100 sulphuric acid.

Iodide-Iodate Method Recommended

The various methods suggested in the literature were subjected to critical examination and comparative tests, with the result that the iodide-iodate method seemed most worthy of further study. This method was subjected to detailed study and with certain minor modifications and attention to details it is herewith recommended as being the most satisfactory method for the accurate analysis for nitrogen in steels. The

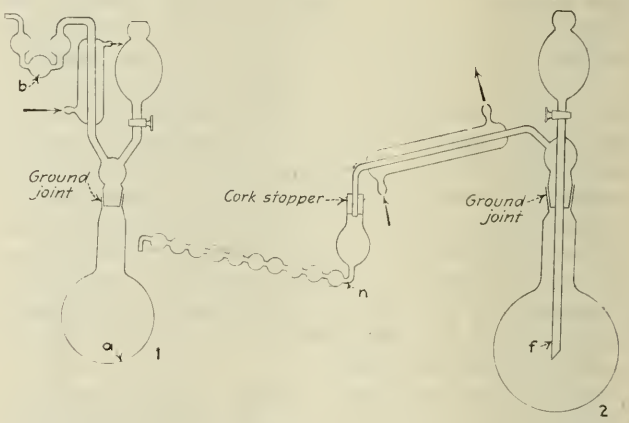

FIG. 1—DISSOLVING FLASK. FIG. 2—DISTILLING FLASK

method has not been tried on high-chromium or high-tungsten steels, but it gives satisfactory results on high-speed steels and all ordinary steels.

Method of Analysis

Apparatus

Dissolving flask should be such as shown in Fig. 1, having a dropping funnel, condenser and bubble tube connected with the flask by a ground glass joint. A convenient size is 200 to 250 c.c.

Distilling flask should be an apparatus such as shown in Fig. 2, consisting of flask, dropping funnel and condenser connected by a ground glass joint. The receiver is a convenient form to use, although a simpler form may be substituted.

Reagents

Pure, ammonia-free water is prepared by distilling distilled water with a solution of alkaline potassium permanganate made by dissolving 200 g. potassium hydroxide and 8 g. potassium permanganate in 1,100 c.c. distilled water, and then concentrating by boiling to 1,000 c.c. This solution is added to the water to be purified in the ratio of 1:10. Distillation is then carried on until a test of the distillate made with Nessler's reagent shows freedom from ammonia. Further dis-

[19] *Jernkontorets Annaler*, 1907.

[21] *Stahl u. Eisen*, 1913, p. 1721.

tillation produces water, which may be collected for use in the analysis. It is advisable to use a condenser tube of tin.

Four hundred grams sodium hydroxide is dissolved in 1 liter of water for this reagent. It is likely to contain nitrites, which might be reduced to ammonia by the ferrous hydroxide when distillation is made during the analysis. Zinc finely covered with deposited copper is used for destroying the nitrites and to some extent the nitrates. The zinc is kept submerged 10 minutes in dilute copper sulphate and washed with distilled water and a small amount of it is permitted to stand for 24 hours at 50 deg. C. in contact with the sodium hydroxide solution.[22] Nitrites are then reduced and the sodium hydroxide solution decanted off. The solution is then boiled in a distilling flask until the ammonia has been expelled. The solution is then brought to the same molal concentration as the hydrochloric acid solution of sp.gr. 1.12. Small amounts of nitrates present do not interfere with the analysis, as they are not easily decomposed by ferrous iron so long as the concentration is low (Braune).

Pure hydrochloric acid will always contain some traces of ammonia and should be purified before being used for dissolving the metal. Hydrochloric acid of 1.124 sp.gr. can be recommended for dissolving the steel sample. Prepare pure hydrochloric acid solution of sp.gr. 1.12 by distilling concentrated hydrochloric solution with addition of a little concentrated sulphuric acid and absorbing the hydrochloric acid gas in pure water, prepared by distilling over potassium permanganate solution.

Potassium iodide and potassium iodate may be obtained free from impurities which affect the analysis. A single recrystallization suffices to remove traces of free alkali. A solution of each salt is prepared by dissolving 5 g. of the respective salt in 100 c.c. of water.

Sodium thiosulphate solution, N/100, is made by dissolving 2.5 g. of crystallized sodium thiosulphate in pure water; dilute to 1 liter.

Sulphuric acid, N/100: Dilute 0.3 c.c. concentrated sulphuric acid with water to 1 liter. Standardize against pure sodium carbonate or by means of barium chloride.

Solution of the Steel

Approximately 5 g. of steel is placed on the bottom of the dissolving flask *a* (Fig. 1). About 7 to 9 c.c. hydrochloric acid (1.12 sp.gr.) is placed in the bulb neck *b*, so as to seal this gas passage. Through the dropping funnel is introduced 40 c.c. hydrochloric acid (1.12 sp.gr.) and the flask *a* is slightly heated. The steel sample will rapidly dissolve, the evolved gases passing through the water-cooled condenser and out through *b*.

Vapors are condensed in the water-cooled tube and returned to flask *a*. Neck *b* washes the evolved gases so that any ammonia which otherwise might be carried off with the escaping hydrogen and hydrocarbon gases will be retained in the hydrochloric acid. The water-cooled condenser should not be omitted, as it is an essential feature of the apparatus.

When the steel has been completely dissolved all the nitride nitrogen remains as ammonium chloride in the flask *a* with the exception of traces of ammonium chloride to be found in the bulbs *b*. The contents of the latter are washed into *a* and the contents of *a* are then washed into the dropping funnel of the distilling flask, Fig. 2.

Distillation of the Solution Containing Ammonium Chloride

In the distilling flask as shown in the sketch is placed at least 50 c.c. of the sodium hydroxide solution, 300 c.c. of water, 10 c.c. of a potassium permanganate solution (8 g. $KMnO_4$ and 200 g. NaOH dissolved in 1,000 c.c. water). On the bottom of the flask is placed small coils of nichrome wire to insure quiet boiling. The liquid is then boiled until part of it is distilled over.

The receiver *n*, containing 10 c.c. N/100 H_2SO_4 or a larger exactly measured amount, is then attached to the condenser and care is taken that the position of the receptacle is kept in such a way that the bend *n* is sealed with the acid. The acid ferrous solution, which up to that moment has been kept in the drop funnel, is then gradually run down into the distilling flask.

The boiling immediately accelerates, as the liquid in the distilling flask will give off ammonia and hydrocarbon gases, and the ammonia together with water vapor begins to collect in the water-cooled condenser and drops will soon run down into the receiver. After a few minutes of boiling all the ammonia has passed over into the receptacle *n* and has combined with the sulphuric acid.

Violent boiling and detrimental shocks are apt to occur when distillation has proceeded for a certain time. For this reason it is advisable to retain a small part of the ferrous solution in the dropping funnel instead of adding all the ferrous solution to the distilling flask at the beginning. When the few remaining drops of acid ferrous solution are finally added to the distilling flask at the end of distillation, additional volumes of hydrocarbon gases revive the boiling of the alkaline liquid and prevent accidents.

When properly handled the process of distillation lasts only a few minutes and sufficient alkaline solution can be kept in the distilling flask to make it possible to run a series of four or five analyses without interrupting the boiling.

Collecting the Distillate in Sulphuric Acid

Before beginning the distillation it is necessary to attach the receiver *n* to the end of the condenser tube as shown in Fig. 2. The connection is made airtight by a cork stopper.

In the bend *n* is the sulphuric acid, which has been carefully measured out from a burette. The sulphuric acid completely seals this bend. Under these circumstances no ammonia can escape, but all of it will be retained as ammonium sulphate in the receiver whether it escapes from the distilling flask as gas or is collected in water drops in the inclined condensing tube. Distillation is continued until about 50 c.c. has been collected in the receiver. The progress of distillation can be readily controlled as one bulb after the other is filled with the distillate and the gases pass through as bubbles. The distillate will always smell strongly of hydrocarbons.

When distillation is finished, the receiver is detached and the distillate, containing all the ammonia as ammonium sulphate, is poured into a small beaker and is titrated. The distillate should always contain an excess

[22] Cit. Braune (Swedish Dept. Testing Materials.)

of free sulphuric acid and this amount of free sulphuric acid must be determined.

The liquid in the receiver, originally consisting of 10 c.c. N/100 sulphuric acid or any other exactly determined volume, is now partly a mixture of ammonium sulphate and free sulphuric acid. After this solution has been transferred to a beaker, 4 c.c. potassium iodide solution and 2 c.c. of potassium iodate solution are added and the liberated iodine is immediately titrated with N/100 sodium thiosulphate.

Immediately after this titration it is necessary to make a second one. For this purpose 10 c.c. N/100 sulphuric acid or exactly the same amount as originally used in the receiver is measured from a burette and the same volume of iodide and iodate solution is added. The idodine set free is again titrated with sodium thiosulphate and the amount of sodium thiosulphate recorded. The difference in the two values represents the amount of sulphuric acid equivalent to the ammonia absorbed.

Notes on the Procedure

Nitrogen exists in steel as iron nitride, Fe_2N, which is readily decomposed by hydrochloric acid with formation of ammonium chloride. Ammonia is set free from ammonium chloride when heated with sodium hydroxide, and may be collected in sulphuric acid, which must be present in excess. Free sulphuric acid, in small amounts, may be determined with great accuracy by making use of the following reaction:

$$5KI + KIO_3 + 3H_2SO_4 = 3K_2SO_4 + 3H_2O + 3I_2$$

The amount of iodine liberated is a direct measure of the sulphuric acid, and consequently of the nitrogen, and may be determined by means of N/100 sodium thiosulphate. When the N/100 H_2SO_4 is measured for the receiver a similar amount should be measured and treated with iodide and iodate so as to get the value of the N/100 $Na_2S_2O_3$. The difference between the amount of iodine liberated in this blank determination and the amount set free in the actual analysis represents the amount of H_2SO_4 not neutralized by the ammonia, and hence gives a value for the amount neutralized. Inasmuch as $3I_2$ is equivalent to $3H_2SO_4$, from the above equation it follows that $3I_2$ is equivalent to 6N, or I_2 is equivalent to N_2. Knowing these values, the nitrogen content of the steel may be calculated.

Sulphuric acid is used as the standard basis for all calculations, as its value remains permanent. Sodium thiosulphate, on the other hand, changes from hour to hour and should always be checked for each series of analyses. It should be checked against the sulphuric acid using the iodide-iodate reactions, and occasionally against iodine, making use of a carefully standardized potassium permanganate and the reaction:

$$2KMnO_4 + 10KI + 8H_2SO_4 = 6K_2SO_4 + 2MnSO_4 + 8H_2O + 5I_2$$

Glass-stoppered apparatus is essential if accuracy is desired. Care should be taken to prevent caustic soda coming in contact with the ground joints, and the joints should always be wet with pure water before closing.

The dropping funnel extends below the liquid in the distilling flask, otherwise there is danger of ferrous chloride spattering on to the hot walls of the flask and liberating hydrochloric acid.

It would be advantageous to have the condenser tube made of tin or quartz, otherwise a blank of about 0.0003 g. nitrogen should be made for each 50 c.c. of distillate.

The presence of hydrocarbons has apparently no effect upon the iodine titration. This was established by adding ammonium chloride in known amount to a hydrochloric acid solution of an annealed high-carbon steel and putting it through the regular operations. In every case the total nitrogen was recovered, even though the distillate smelled strongly of hydrocarbons. In this respect this method has decided advantage over the Nessler method.

The following different steel samples were analyzed and the results are given as characteristic with regard to nitrogen in ordinary steel samples. The analysis shows that the amount of this element present is very small in the cases examined, particularly in the three high-speed steels. Several analyses are given below:

Steel	N as Nitride Per Cent
Swedish crucible steel	0.0006
High-speed steel No. 1	0.0011
American ingot iron	0.003
High-speed steel No. 2	0.0005
High-speed steel No. 3	0.0005
Tool steel No. 1	0.011
Crucible steel	0.011

From this table it seems that with the exception of the tool steel No. 1 the amount of nitrogen is apparently negligible. In this exceptional case, however, it may rank in influence probably with other impurities such as sulphur and phosphorus, and should not be omitted from a complete analysis statement.

In steels which have been case-hardened by almost any of the commercial methods, the nitrogen content may rise to as much as 0.50 to 0.75 per cent.[23]

The Tanning Industry in Russia

Commerce Reports for Jan. 23, 1922, reproduces a statement appearing in the bolshevik press to the effect that 1,775 tanneries, large and small, were in operation at the end of June, 1921, in the whole of Soviet Russia. During the first 6 months of 1921, the statement indicates, 3,451,000 hides were tanned, as compared with a total of 2,700,000 for the same period in 1920, an increase of about 28 per cent. The actual production during the first half of 1921 represents 88 per cent of the prearranged program of production of the tanneries, according to the bolshevist statement.

Since the decree was issued some time ago permitting private persons to engage once more in the operation of industrial establishments a considerable number of the tanneries, all of which had been "nationalized," have been leased for private operation.

The government has retained a number of the larger tanneries, however, and will continue to operate them as government properties.

Vapor Luster on Pottery

An investigation of lusters for pottery decoration has recently been made by the Bureau of Mines to determine the most suitable glaze compositions for taking vapor lusters. Luster decorations are applied to pottery by two methods: First, by applying in paste condition suitable metallic salts to the surface of the ware and firing at a dull heat; second, by vaporizing such salts in the flame of iridescent effects similar to that of favrile glass. Results indicated that glazes containing B_2O_3 and PbO produced the best luster effects, the intensity of the luster increasing with larger amounts of these two components in the glaze.

Industrial Uses of Phosphoric Acid and Phosphates

Phosphoric Acid Is Employed in Clarifying Sugar, Preparing Soft Drinks and Pharmaceuticals—Use of Calcium Acid Phosphate in the Production of Baking Powder and Self-Rising Flour—Formulas for Preparing Food Phosphates—Consumption of Sodium Phosphates

By JACOB T. MECKSTROTH
Chemical Engineer, Columbus, Ohio

THE phosphate industry, as distinguished from the fertilizer industry, may be divided into three groups—viz., (1) the use of phosphoric acid as such, (2) the use of phosphate of calcium, and (3) the use of phosphate of sodium.

The only phosphoric acid of commercial importance is the ortho acid, the chemical formula being H_3PO_4. This is sold in various densities and purities, depending upon the uses to which it is applied. The more important uses are covered in the following paragraphs.

Clarification of Sugar Solutions

Undoubtedly the greatest consumption of phosphoric acid as such is in the clarification of sugar juices in the sugar refineries, large quantities being manufactured for consumption in the cane refineries of this country, Cuba and South America. Various densities may be used and it must be free from arsenic and other deleterious substances. Iron and aluminum salts need not be removed to any great extent, and certain amounts of monocalcium phosphate are generally present.

Often a solution of commercial phosphoric acid, containing a certain amount of dissolved monocalcium phosphate, is concentrated to form a phosphoric acid paste, containing between 47 and 50 per cent of available P_2O_5. This is shipped in casks, and the present prevailing price is about 10c. per lb. of available P_2O_5. Some manufacturers produce a semi-dry mixture of commercial phosphoric acid, which has been properly purified to remove all deleterious substances, and a silicate base, such as fullers earth, Filter-cel, or kieselguhr. This semi-dry compound contains between 38 and 40 per cent of available P_2O_5, and has the advantage that it may be shipped in the regulation flour barrels or in wooden boxes without the difficulty of leakage. It is, therefore, especially desirable for the export trade.

The advantages of phosphoric acid claimed over other clarifying agents are better color of the finished sugar, more rapid crystallization and greater yields. Phosphoric acid in this industry is called a defecating, flocculating and clarifying agent, and the process is called defecation of sugar juices. The raw sugar solution is treated first with lime, the lime combining chemically, is in turn neutralized by the phosphoric acid, an insoluble lime phosphate being formed. The flocculent precipitate is left standing to settle out, or is removed by filtration. The resultant clear solution is evaporated to the required density, cooled, and a snow-white sugar crystallizes.

Jellies—Preserves—Soft Drinks

Considerable phosphoric acid is used in the jelly and preserving industry. Again various densities and purities are used. Acid is sometimes added to the jelly and preserve stock during the boiling period; sometimes only a portion is added at that time, and an additional portion added at the time the jelly is poured into the glasses. This process is chemically controlled, and very exact factory control must be exercised in order to produce a uniform product. The taste and mechanical properties of a jelly are influenced by the addition of too small or too large an amount of the acid.

During the scarcity of tartaric acid and citric acid, considerable phosphoric acid was used in the preparation of soda fountain beverages and bottled soft drinks, but the requirements as to purity for this purpose are very rigid and it is claimed by some of the phosphate manufacturers that the consumption of this acid by the beverage trade is declining. One pound of high-grade phosphoric acid, containing approximately 40 per cent of P_2O_5 or 55 per cent of H_3PO_4, is equivalent in acidity to 0.75 lb. of commercial tartaric acid, or 0.7 lb. of commercial citric acid. Some contend that the phosphoric acid, on account of its pharmacological properties, should not be used in place of the above organic acids, while others claim that on account of the small amount of acid thus consumed by each individual it is not harmful and that on account of its much lower cost it has a distinct advantage commercially.

Medical and Pharmaceutical Compounds

For the preparation of medical and pharmaceutical compounds, sirupy phosphoric acid (85 to 88 per cent H_3PO_4) is mainly in demand. This acid is fairly pure and is made entirely from phosphorus by the so-called electric furnace or distillation process. For some purposes, however, such as the manufacture of hydrogen peroxide, acids of lesser purity are suitable, some being iron free and others having certain impurities removed to suit particular requirements. In the manufacture of metal glycerophosphates, an acid of approximately 42 deg. Bé. (50 per cent H_3PO_4), sulphate free and of low mineral content is required.

A small amount of phosphoric acid, generally about 50 per cent in strength and of different purity, is used for pickling and for the manufacture of rustproofing compounds in the metal industry. An insoluble iron phosphate, it is claimed, is formed, which is not acted upon either by the oxygen of the air or affected by moisture.

Monocalcium Phosphate

By far the largest amount of phosphoric acid is used by the phosphate manufacturer in the production of phosphates of calcium and of sodium. Small amounts of phosphates other than calcium and sodium, such as phosphates of potassium, aluminum, ammonium and magnesium, are produced, but their use is limited.

Monocalcium phosphate, or calcium acid phosphate, $CaH_4(PO_4)_2$, finds its largest uses in the manufacture

of baking powder and self-rising flours. This industry is about 50 years old in America and today there are eleven different phosphate plants in the United States.

Phosphate Rock Present Raw Material

Up to 15 years ago practically all the phosphates of calcium and sodium were made from bone, but as the consumption increased, it became apparent that, if the industry was to have a permanent growth, a product of highest purity was necessary. As a result of research work, processes were developed and perfected for the utilization of the ordinary mineral phosphate, tricalcium phosphate, $Ca_3(PO_4)_2$, with an admixture of calcium fluoride, iron and aluminum phosphate, so extensively mined in Tennessee and Florida. Today probably 95 per cent of all the calcium phosphate going into food products is of mineral origin and is of vastly higher purity than that formerly produced. Owing to the very large capacity in this country, competition is keen and prices have practically receded to pre-war levels.

Baking Powder Indusiry

The monocalcium phosphate is considered the most economical and superior acid ingredient for baking powder manufacturing purposes. It is true that the price of sodium aluminum sulphate is lower, but a large percentage of this acid ingredient causes a better aftertaste in the baked goods.

When the acid phosphate is mixed with bicarbonate of soda and corn starch in proper proportions, and after the complete reaction in baking, no disagreeable and objectionable taste or residue is left in the baked goods. The acid phosphate of calcium is universally used. Monosodium phosphate is also employed in limited quantities, but is considered to be inferior to the calcium acid phosphate for this purpose. The acid phosphate of calcium is often used in combination with sodium aluminum sulphate, cream of tartar and tartaric acid in leavening compounds, also in the compounding of cream of tartar substitutes (C. T. S.).

The granulation or size of granules of the calcium phosphate plays an important part in the action and keeping quality of a baking powder. The finer the phosphate is ground the more readily it will dissolve. When used in combination with sodium aluminum sulphate, the phosphate, being the more soluble, acts first on the bicarbonate of soda and as the baking proceeds the sodium aluminum sulphate dissolves and acts with the remaining bicarbonate of soda. The granulation of the phosphate not only influences the rate of reaction, but also determines the keeping quality of the baking powder. The phosphate manufacturers produce both a powdered and a granular grade, each grade serving its particular use and purpose. In the so-called "straight phosphate powder" a granular phosphate and soda should be used. Not only will a powdered phosphate cause premature reaction, but will also react too fast during the baking process. A baking powder produced from both powdered phosphate and powdered soda will show considerable deterioration at the end of a few weeks, while a powder produced by the use of both granular phosphate and granular soda will show very little deterioration even at the end of 6 months.

The average composition of a phosphate baking powder for household use should be as follows:

25 to 28 per cent bicarbonate of soda (granular).
33 to 37 per cent calcium acid phosphate (granular).
42 to 35 per cent re-dried corn starch (5 to 8 per cent moisture).

For bakery and hotel uses the formula should be:

30 to 35 per cent of bicarbonate of soda (granular).
40 to 46 per cent of calcium acid phosphate (granular).
30 to 19 per cent of re-dried corn starch (5 to 8 per cent moisture).

In the formula it is seen that 0.75 lb. of bicarbonate of soda is neutralized by 1 lb. of calcium acid phosphate. In other words, calcium acid phosphate is used as a neutralizing agent at a neutralizing strength of 75 per cent in terms of bicarbonate of soda. The neutralizing strength is sometimes used at 80 per cent instead of 75 per cent. Some manufacturers reduce the high strength phosphate by the addition of a high-grade corn starch, either during the wet process of manufacture or during the final standardization by mixing in a dry state. In this manner the phosphate is made to any strength desired and the method has its advantages and disadvantages.

Self-Rising Flour

Thousands of tons of self-rising flour, examples of which are the prepared soft wheat flour (for hot biscuits), pancake flour and cake flour, are manufactured and consumed every year in this country. A standard formula cannot be given for preparing all the above flours. As a basis the following formula may act as a guide in the compounding of a self-rising flour. To every 92 lb. of flour and 2½ lb. of bicarbonate of soda, 3⅓ lb. of 75 per cent strength calcium acid phosphate and 2½ lb. of edible salt; or to every 92 lb. of flour add 2½ lb. of bicarbonate of soda, 3⅓ lb. of 80 per cent calcium acid phosphate and 2½ lb. of edible salt.

Usually the powdered soda and powdered phosphate are used, since the flour acts as the separatory agent and prevents a premature reaction and decomposition. The moisture in the flour, however, must not be too high, as it influences very materially the keeping quality of the prepared product. At no time should a self-rising flour be prepared in large quantities without first testing out the formula in a trial baking test, and the moisture and quality of all the ingredients should be carefully determined. The color and odor of the phosphate are very important, as no manufacturer of self-rising flour will permit addition of dark color or noticeable foreign odor to his product.

Sodium Phosphates

The uses of sodium phosphates in the industries is very extensive and, according to the U. S. Geological Survey, over 30,000 tons valued at about three and one-quarter million dollars were manufactured in 1920.

Monosodium phosphate has a limited use. As ordinarily manufactured, it is very hygroscopic and not suitable for either baking powder or self-rising flour. However, by a patented process it is now manufactured in a non-hygroscopic state and is used to some extent. It is considered inferior to calcium acid phosphate for these purposes.

Disodium phosphate is also a commodity used in a large way in the dyeing and textile industries, for water softening, medicinal and dental purposes and in the arts generally.

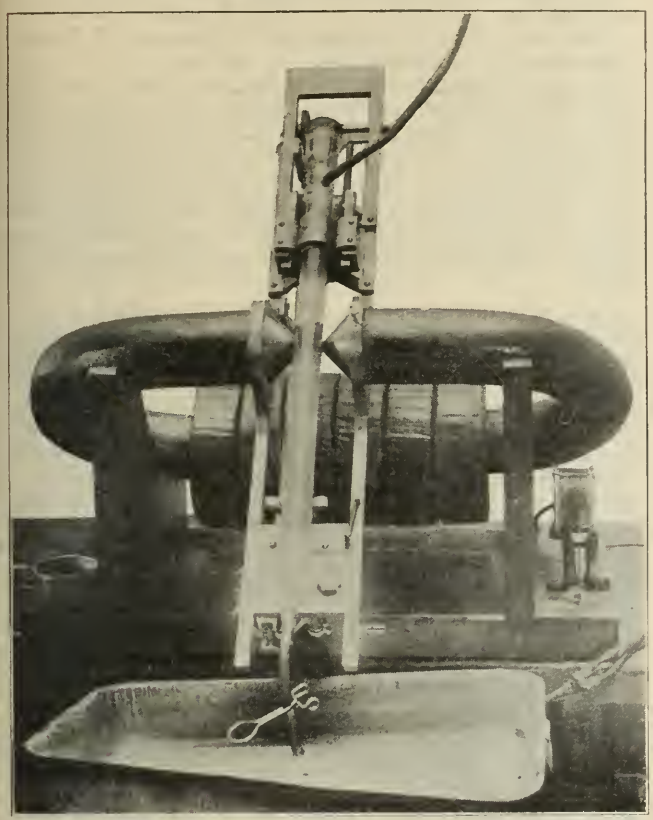
Trisodium phosphate is the most important of the sodium group. This finds extensive use in the preparation of boiler compounds in the laundry, paper industries, etc.

Acid sodium pyrophosphate is a product which finds some use in bake shops and restaurants as a substitute for cream of tartar.

Davis Tube Analyzer for Magnetic Assays

The Davis Tube Analyzer is a simple device for quickly reducing a sample of ore so that the magnetic iron percentage can be accurately computed. It was developed by E. W. Davis, head of the Experimental Mines Station of the University of Minnesota. The device is now being manufactured by the Dings Magnetic Separator Co., of Milwaukee.

Briefly, its operation is as follows: A sample of ore is placed in the glass tube, shown in the illustration,



DAVIS TUBE ANALYZER FOR MAGNETIC ASSAYS

which has previously been filled with water. The carriage bearings are placed at the poles of the magnet. A stream of water passes through the tube, washing away the tailing from the concentrate, which is held at the poles. When the washing is completed, the concentrate and tailings are dried, weighed and analyzed. A complete computation for magnetic iron may be made when the soluble iron assays of the feed, concentrate and tailing and the weight of the concentrate are known.

Summary of New Oil Companies

During December, 1921, fifty-eight new companies with individual capitalization of $50,000 or more were organized to engage in different branches of the oil industry. The aggregate indicated capital is $65,615,000. This compares with the November record of seventy-one such new companies with a total indicated capital of $60,129,000. The corresponding figures for December, 1920, show ninety-five new oil companies with aggregate capitalization of $108,680,000.

Comparing the two years, the 1921 records set forth a total of 936 companies of this character organized, with combined indicated capital of $1,255,657,000. The 1920 figures stand at 1,712 such new companies, with combined capitalization of $2,786,814,000.

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Desulphurizing Gases.—Coal gas is first purified by treatment with a washing liquid such as moderately concentrated sulphuric acid or passed through charcoal to remove certain tarry constituents, and is then passed through a reaction vessel in which it is treated with active charcoal in the presence of oxygen or air. The sulphur in the gas as sulphuretted hydrogen is deposited on the active charcoal, and may be extracted by a solvent, the charcoal being re-used. A small amount of ammonia or ammonium carbonate may be added to the gas entering the reaction vessel or to the catalytic mass therein, after purification with an acid. The porous mass in the purification vessel is either replaced at intervals or revivified by solvents or steam. (Br. Pat. 170,152. Badische Anilin- & Soda-Fabrik, Ludwigshaven-on-Rhine. Nov. 30, 1921.)

Slow Setting Cement.—A slow setting cement free from calcium aluminates and ferrites is prepared by adding ferric oxide to the usual ingredients of portland cement, so that the ratio of ferric oxide to alumina is between 1 and 1.563 to 1. Siliceous sand is also added to restore the ratio of silica to sesquioxides to the normal value. The materials are treated in the usual manner. (Br. Pat 170,063. Bombrini Parodi-Delfino, Rome. Nov. 30, 1921.)

Viscose Filaments.—The salts carried by or found on the threads after leaving the acid precipitating bath are recovered and utilized by washing the threads with dilute sulphuric acid so as to form the very soluble bisulphate of soda or potash, and then returning the resulting acid salt solutions, after concentration, to the precipitating bath. For the washing a 10 to 12 per cent sulphuric acid solution is preferably employed. (Br. Pat. 170,316. E. Bronnert, Mulhouse. Dec. 7, 1921. Br. Pat. 170,322 and 170,313 by the same patentee, Dec. 7, 1921, refer respectively to the addition of lactic acid to the sulphuric acid precipitating bath employed in spinning viscose filaments and to a modification in the precipitating bath in which a solution of common salt or waste stassfurt salts and sulphuric acid is used.)

Pigments.—In producing pigments consisting of a true pigment and an "extender," such as barium sulphate, by precipitating the extender in the presence of the suspended pigment or precipitating the two simultaneously, the solutions employed are so dilute or the precipitating reagent is added so gradually as to cause the formation of barium sulphate in the colloidal state. The resulting pigment is separated by filtration, dried and ground. (Br. Pat. 170,431. J. C. Smith, London. Dec. 7, 1921.)

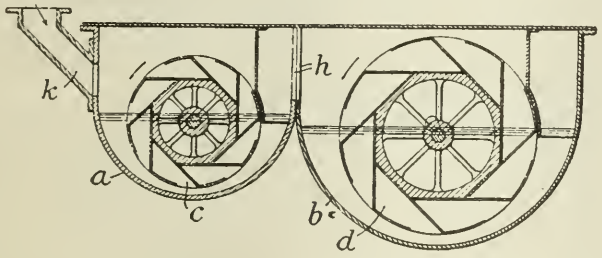
Flux for Welding Aluminum.—A flux for the autogenous welding of aluminum comprises one or more alkali halides and an activating agent which reacts with them only in the presence of aluminum oxide. An alkali pyrosulphate or pyrophosphate is employed as activating agent, a suitable mixture being potassium chloride 45 per cent, sodium chloride 30 per cent, potassium fluoride 7 per cent, lithium chloride 15 per cent, and the pyrosulphate or pyrophosphate 1 to 10 per cent. The materials are all melted together in a vessel free from metallic oxide soluble in the flux, and on solidifying a homogeneous mass remains, which is powdered. (Br. Pat. 170,343. H. V. A. Briscoe, D. Richardson and District Chemical Co., Ltd., all in London. Dec. 7, 1921.)

Urea; Fertilizers.—Urea is obtained by heating cyanamides with water and neutral or basic salts or alkali or alkaline earth metals. The water may be added wholly or in part as water of crystallization of the salt employed, or

steam may be led in; catalysts such as oxides of iron or manganese may be added, or the reaction effected under pressure. In an example, calcium cyanamide is heated with water and crystallized calcium nitrate; the calcium oxide present in commercial calcium cyanamide may be previously in part or wholly neutralized by acids such as carbonic or sulphurous acids. The products may be obtained in granular form for use as fertilizers, and there may be used in the process other salts which are themselves fertilizers—for example, potassium salts. (Br. Pat. 170,329. E. Lie and Aktieselskabet North Western Cyanamide Co., Odda, Norway. Dec. 7, 1921.)

Ammonium Sulphate.—In the production of ammonium sulphate by passing into a saturator gases which are likely to contain cyanogen compounds, the cyanogen compounds are prevented from reaching the saturator by adding to the ammoniacal liquor to be distilled a polysulphide, or forming a polysulphide in the liquor—for instance, by adding sulphur or blowing in air—so as to fix the cyanogen compounds in the liquor as sulphocyanides; or the vapor from the still may be passed over spent oxide on its way to the saturator. In the case of the direct process, the ammoniacal gas is passed through a washer containing a polysulphide solution. (Br. Pat. 170,613. South Metropolitan Gas Co. and P. Parish, London. Dec. 14, 1921.)

Recovering Gases and Vapors Absorbed in Solids.—For recovering gases or vapors absorbed in solids such as charcoal or alumina, the solid is caused to travel through a bath of liquid metal, for example of molten lead, heated to the requisite temperature, or through a series of such baths



maintained at gradually increasing temperatures so as fractionally to expel the gases; in the latter case the heated solid may be returned to the bath of lower temperature so as to carry into the latter, heat acquired in the bath or baths of higher temperature. When recovering ethylene, etc., which has been absorbed from coal or other gas, the saturated charcoal may first be passed through a bath of molten alloy maintaned at about 120 deg. C., and then through a bath of molten lead at about 350 deg. C.; the charcoal is afterward cooled by passage through the first bath, through a bath of cooled mercury, or by the stripped and cooled gases; and benzene may be recoverd from the charcoal of the preliminary absorbers in a similar manner, but generally these will be charged with charcoal already saturated with ethylene. A convenient apparatus comprises baths *a*, *b* arranged close together and each containing two pairs of rotating paddles *c*, c^1, *d*, d^1; the charcoal enters the bath *a* by a shoot *k*, is carried beneath the molten metal by the paddle *c*, falls through the adjacent openings *h* into the bath *b*, is carried there through by the paddle *d*, then passes to the other side of the bath, and is carried back in a similar manner by the paddles d^1, c^1, (not shown) which rotate in an opposite direction to the paddles *d*, *c;* the gases which escape are collected separately and are led away through outlets in the cover. (Br. Pat. 170,323. Thermal Industrial & Chemical Research Co. and J. S. Morgan, Westminster. Dec. 7, 1921. Br. Pat. 170,617 by the same patentee, Dec. 14, 1922, covers the application of the molten metal bath to the heating of liquids, such as tar.)

Viscose Silk.—The precipitating bath employed in the manufacture of artificial silk from raw viscose consists of sulphuric acid, which is at least partly bound to aromatic radicals. Examples are given of baths containing sodium benzene sulphonate and free sulphuric acid. The acid mixtures obtained in the direct sulphonation of benzene and its homologs, and of phenol, naphthol and their homologs may be employed. (Br. Pat. 170,029. E. Bronnert, Mulhouse. Nov. 30, 1921. Patents 166,931 and 170,024 refer to the process of spinning, using the above precipitating bath. The use of a bath of highly concentrated solution of bisulphites with or without formaldehyde or glucuse is covered by Br. Pat. 170,874, by the same patentee, Dec. 21, 1921.)

Concentration of Ores.—In a froth-flotation process, products obtained by treating viscous substances such as tars, fuel oil or tar oil with emulsifying agents such as caustic alkalis, carbonates, soaps, sodium resinate or mixtures thereof, are used as frothing agents or as a source of or in conjunction with frothing agents. For example, producer-gas tar may be heated with an aqueous solution of caustic soda. (Br. Pat. 170,944. W. G. Sellers and Minerals Separation, Ltd., London. Dec. 21, 1921.)

Sulphite Cellulose.—Wood is cleaned, split into small pieces, and treated with dilute sulphuric acid under pressure, drained and neutralized. The wood lignine is thus decomposed and is subsequently dissolved by boiling in known manner with calcium or magnesium-calcium bisulphate under pressure, yielding a nearly pure alpha-cellulose particularly suitable for making pure viscose and cellulose acetate. (Br. Pat. 170,964. E. Bronnert, Mulhouse. Dec. 21, 1921.)

Calcium Superphosphate.—Phosphatic minerals are pulverized, subjected to a froth-flotation process to separate undesirable constitutents, and finally treated with sulphuric acid. In examples in which crude phosphorite and waste phosphatic material rejected after hand-picking are used as the starting material, the mineral after grinding is agitated and aërated with water containing oelic acid as the frothing agent. Sodium silicate is also added to wet effectively the constituents which are not to be floated. The froth is drained or mechanically filtered, and the resulting damp powder treated with sulphuric acid. In place of oleic acid other frothing agents such as soap may be used, and when the water is hard a small amount of sodium resinate should be added. The frothing agent may be emulsified by adding sodium oleate or sodium resinate before mixing with the mineral pulp. When it is necessary to repeat the flotation process, the concentrate is agitated and aërated with water containing sodium silicate without the addition of oleic acid or other frothing-agent. (Br. Pat. 171,155. W. Broadbridge and E. Edser, both in London. Dec. 30, 1921.)

Artificial Silk.—Relates to modifications of the processes for spinning the finest threads of viscose silk, using the ordinary spinning apertures of 0.1 mm. diameter. According to the present invention, artificial resins prepared by the condensation of phenols with formaldehyde are added to the viscose before spinning and preferably before ripening. As spinning baths, concentrated solutions of bisulphite of soda, alone or with the addition of ammonium bisulphite, are employed and the concentration of the bath is maintained, higher according as the threads are finer. By this addition it is stated that the threads take darker shades in the dye bath, and that their resistance to water is increased. (Br. Pat. 171,125. E. Bronnert, Mulhouse, Dec. 30, 1921.)

Insulating Coatings for Metals.—In coating metal and other surfaces with phenol-formaldehyde condensation products or resins such as Bakelite and asbestos, blistering is prevented by coating the surface with the resin, applying asbestos paper or the like, hardening the resin by heat, and then impregnating the asbestos with liquid or dissolved resin which is finally hardened. (Br. Pat. 171,369. Not yet accepted. J. K. Wirth, Berlin. Dec. 31, 1921.)

Metal Carrier for Catalyzers.—The carrier or support for a catalyst for chemical reactions, particularly the production of acetone from acetic acid, is made of a metal or an alloy. Aluminum is specially suitable, for by vigorously stirring the molten metal as it cools, rough porous granules are produced, upon which the catalyst can be deposited by boiling the granules in a solution or suspension thereof. For acetone production, acetic acid vapor is conducted through a tube heated to 300 to 400 deg. C., and containing as catalyst an oxide, hydrate, carbonate or acetate of calcium or barium supported upon the metallic carrier. (Br. Pat. 171,391. Not yet accepted. Stockholms Superfosfat Fabriks Akiebolag, Stockholm. Dec. 31, 1921.)

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields—Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Managing Editor of Chem. & Met. to Go to Europe

In accordance with editorial plans for 1922, announced in CHEM. & MET. on Jan. 4, the Managing Editor of this magazine, J. S. Negru, will sail for Europe on Feb. 11. He will be gone for at least 6 months, and during that time will make a trip through Germany, France, Belgium and other European industrial countries. The purpose of the trip is to study industrial and economic conditions and observe the latest advances in science and engineering.

Mr. Negru is unusually well qualified to undertake this work, which should prove distinctly serviceable to the readers and advertisers of CHEM. & MET. He is a native

J. S. NEGRU, MANAGING EDITOR OF CHEMICAL & METALLURGICAL ENGINEERING

of Europe, a graduate engineer from the University of Liége, and consequently familiar with European conditions and widely acquainted among European engineers. For the past 16 years he has spent a large portion of his time in the United States, acquiring a broad experience in American industrial practice, which will enable him to co-ordinate his observations abroad with conditions in this country. Added to this engineering and industrial experience is the fact that he has for nearly 3 years been the Managing Editor of CHEMICAL & METALLURGICAL ENGINEERING, where he has acquired our viewpoint of service to the industry.

It is expected that through Mr. Negru the magazine can reflect industrial conditions in Europe and interpret them to the mutual benefit of American and European manufacturers and consumers.

Federated American Engineering Societies Appoints Committees

The Federated American Engineering Societies has appointed a new committee on registration of engineers. The personnel of the committee is as follows: A. S. Dwight (chairman), New York; Gardiner S. Williams, Ann Arbor, and Philip N. Moore, St. Louis.

A new federal water power committee also has been named. John H. Finney, Washington, is the chairman of the committee. Other members are Calvert Townley, New York; G. S. Williams, Ann Arbor; Gano Dunn, New York, and A. P. Davis, Washington.

Dye Investigation Sub-Committee Finally Complete —Hearings to Begin Promptly

With the acceptance by Senator Ernst of Kentucky of an assignment on the sub-committee which will conduct the dye investigation recently ordered by the Senate, the early opening of the hearing is assured. The sub-committee has held an executive session at which plans for the conduct of the hearing were discussed.

It is the intention of the sub-committee to hear first the witnesses who will be called in an effort to establish that there is a monopoly in the manufacture of dyes in this country and that the domestic industry is engaged in improper activities in an effort to influence legislation. Up to the present time no date has been fixed for an open hearing and no announcement has been made as to the witnesses that will be called first.

New Head of Paper Division of Bureau of Commerce

Grosvenor M. Jones of Cleveland has been appointed by the Secretary of Commerce to be chief of the Paper Division of the Bureau of Foreign and Domestic Commerce. Mr. Jones has had considerable experience in the paper industry and trade both officially and unofficially. In 1913, before entering the service of the Bureau of Foreign and Domestic Commerce, he was engaged in a special investigation in Washington in behalf of American Paper and Pulp Association.

He was assistant director of the Bureau of Foreign and Domestic Commerce from February, 1918, to August, 1919. He has traveled in Europe and in Latin America in behalf of the Department of Commerce, studying industries, ports and shipping. Mr. Jones visited Central America in 1919 in connection with the second Pan-American financial conference. He was then appointed assistant manager of the Mercantile Bank of the Americas, followed later by appointment as director of that bank's Peruvian branch.

Mr. Jones attended Harvard University and is a graduate of Georgetown University, where he received his LL.B.

Patent Office Relief Bill Reported Favorably to Senate by Committee on Patents

The Patent Office relief bill was advanced another step in its legislative course Jan. 24 when the Senate Committee on Patents reported the bill to the Senate with the recommendation that it be passed without amendment. Senator Johnson of California, the chairman of the committee, states that every effort will be made to obtain consideration of the bill at the earliest moment.

It is understood that Senator Norris of Nebraska, formerly chairman of the Senate Patent Committee, will offer as an amendment the proposal to allow the Federal Trade Commission to administer patents for employees of the

federal government. It was this rider which killed the Patent Office bill at the last session of Congress. The chances are that the Norris amendment can be brought to a vote promptly, and if defeated the final enactment of the legislation would be a matter of a very few days. Should the Senate feel obliged, for the sake of consistency, to support its former action and vote the Norris provision into the bill, the delays incident to a divided conference committee and a possible fight on the conference report would loom.

Varnish Company Establishes Industrial Museum in Connection with Technical Library

The Murphy Varnish Co., Newark, N. J., has established an industrial museum, the first of its kind in the city, in the rooms formerly used as offices by the Essex Varnish Co., now a part of the Murphy plant, totaling about 800 sq.ft. of floor space. The museum is designed primarily for visitors to the factory, and presents an interesting exhibit of raw materials, processes and finished products of the company. A fine photograph collection sets forth methods of operation from the gathering of raw materials to different features of plant production. The finished products are displayed in company with articles upon which they have been used, such as clocks, buttons, electrical apparatus, stampings, etc. A technical library for employees at the works has been established in connection with the museum, containing about 350 volumes, pertinent to paint and varnish manufacture, selling, advertising, business methods and the like. Technical magazines and other periodicals are also on file.

Industrial Optimism Justified by Many Increases of Operating Programs

Glass.—The Allegheny Window Glass Co., Port Allegheny, near Kane, Pa., has arranged for the immediate resumption of operations at its local plant, following a shutdown for the past 13 months. Employment will be given to about 1,300 workers.

The Whitall-Tatum Co., Millville, N. J., manufacturer of druggists' glassware products, resumed operations on Jan. 17 at four of its local plants recently closed down through lack of orders.

Practically all of the glass-manufacturing plants at Tarentum and Brackenridge, Pa., are now in operation on nearly normal production schedules.

The Millville Bottle Works, Millville, N. J., manufacturer of druggists' glassware specialties, has completed the construction of a new 12-pot plant, and will place the unit in operation at once.

Paper.—The International Paper Co., New York, N. Y., will commence operations at its plant at Three Rivers, near Montreal, early in Feb., with an initial production of about 100 tons of newsprint paper per day.

Leather.—The New Castle Leather Co., Wilmington, Del., specializing in the production of morocco leathers, has increased the working force at its tannery to the normal quota of 750 persons for the first time in the past 4 years.

Tin.—The N. & G. Taylor Co., Cumberland, Md., manufacturer of tinplate, has increased the force of operatives at its local plant. The present basis of production is better than 50 per cent.

The Follansbee Brothers Co., Pittsburgh, Pa., has commenced production at its new tin mills at Toronto, Ohio. Two sheet mills at the plant were opened recently and arrangements are being made for the early operation of all departments at the plant.

Effective Jan. 17, the McKeesport Tin Plate Co., Portvue, near McKeesport, Pa., resumed operations at twenty hot mills, fifty-nine tin stacks and cold mills at its local plant, giving employment to about 1,500 workers. Operations will be resumed at other hot mills at an early date.

The American Sheet & Tin Plate Co., Farrell, Pa., has placed two additional hot mills in service at its local works, giving employment to about 100 extra men. A gradual increase will be made in production until capacity is reached.

Cement.—The Bessemer Limestone & Cement Co., Youngstown, Ohio., is maintaining capacity operations at its mills, and has already booked orders for 200,000 bbl. for delivery in 1922, or about one-sixth of the plant capacity. It is expected that 80 per cent of the 1922 output will be sold for the year within a short time.

Zinc.—The New Jersey Zinc Co. is operating above normal production at its properties at Millport and Hazard, near Palmerton, Pa., giving employment to about 150 more men than in 1914.

Asbestos.—In connection with the maintaining of regular production at its different plants, the Johns-Manville Co., New York, has restored the 10 per cent wage cut of certain employees, placed in effect last October. The reinstatement will be operative from Jan. 1.

Iron and Steel.—The Trumbull Cliffs Furnace Co., Warren, Ohio, has blown in its new 600-ton blast furnace. The furnace and auxiliaries represent an investment of about $3,000,000. There are more furnaces in blast in this district now than at any time since February, 1921.

The Carnegie Steel Co. is now operating five of the six blast furnaces at its Ohio mills.

The Glasgow Iron Co., Pottstown, Pa., resumed production at seven of its local puddling furnaces on Jan. 17.

The Trumbull Steel Co., Trumbull, Ohio, has increased operations from ten to nineteen mills at its plant.

University of Illinois Offers Assistantships in Engineering Experiment Station

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen research graduate assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics or applied chemistry.

An appointment to the position of research graduate assistant is made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Not more than half of the time of a research graduate assistant is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the director of the station each year not later than the first day of March. Additional information may be obtained by addressing the director at the University of Illinois, Urbana, Ill.

Foundrymen Change Convention Plans

It has been previously announced that the annual convention and exhibit of the American Foundrymen's Association would be held in Cleveland the week of April 24. Due to the incomplete condition of Public Hall, uncertainty as to when it would be open to the public and the manner in which it would be operated made it impossible for the city of Cleveland to give a lease for any specific date in 1922. Because of these conditions the present administration could not honor the agreements which the previous administration had entered into with the association. Rochester had previously extended a cordial invitation for this year's meeting, backed by assurances of 100 per cent support on the part of Rochester foundries and other civic bodies. All these were promptly reaffirmed by Rochester, with the result that this city has been chosen for a convention to be held during the week of June 5.

New Haven Section, A.C.S., Elects

At the annual meeting of the New Haven Section of the American Chemical Society the following officers were chosen for 1922: President, Milo C. Burt; vice-president, Treat B. Johnson; secretary, Blair Saxton; treasurer, John L. Christie; councilor, Harold Hibbert.

English and American Crucible Steels Compared at Society for Steel Treating Meeting

T. Holland Nelson, steel works manager, Henry Disston & Sons, Philadelphia, spoke before the Washington Chapter of the American Society for Steel Treating, Jan. 20, discussing American and English methods of producing high-grade crucible steels. He contrasted particularly the methods of manufacture as affecting the uniformity and real value of the product of the two countries. Emphasis was laid particularly upon the greater use of Swedish iron by the English manufacturers, not so much because of any advantage that can be revealed by analysis or microscopic examination as because practical experience indicates that a more uniform product can often be made from the Swedish iron.

Mr. Nelson also warned against acceptance of tool stock as hammered bars when really the material offered as such is only rolled bar stock given a finishing treatment under the hammer. The extra cost and extra price charged for such hammer-finished bars is not, in Mr. Nelson's judgment, at all worth while to the purchaser for tool manufacture. However, he does point out a definite advantage under some circumstances for genuine hammer stock in contrast with rolled bar stock.

Italian Chemistry Subject at Chicago Section, A.C.S.

Dr. William McPherson, chairman of the department of chemistry at the Ohio State University, spoke before the Chicago Section of the American Chemical Society, Jan. 20, on his experiences in visiting the Italian universities. Although not so well known as they deserve to be, Italian universities have behind them a history in the advancement of science that is highly commendable. Dr. McPherson spoke of the charm of the old universities where such noted men of science as Galvani, Volta and Avogadro carried on their work, many of which have the laboratories located in the courts of old monasteries, most adaptable places for such work because of their quiet atmosphere and the fireproof construction of the buildings. Dr. McPherson showed many slides of the various buildings and interiors of laboratories and spoke at length on the more noted men in Italy.

Louisiana Leads in Training Sugar Chemists

John M. Parker, Governor of Louisiana, made the following statement to the Senate Committee on Finance on Jan. 23, during the course of an argument for the tariff on sugar:

"Louisiana has done more for the sugar industry of the world than any other single community. At this time we have sixty-seven men from different nations studying sugar chemistry at Louisiana State University. There, sugar chemistry has been worked out in a very advanced way and that knowledge is being utilized all over the world."

Joint Meeting of Four Societies in New York Feb. 10

"Research in Chemistry as Related to Medicine" will be the subject of an address to be delivered by Dr. Russell H. Chittenden of the Sheffield Scientific School, Yale University, before a joint meeting of the New York sections of the American Chemical Society, the American Electrochemical Society, the American sections of the Société de Chimie Industrielle and the Society of Chemical Industry on Feb. 10, at Rumson Hall, New York. The address will be followed by a discussion by C. H. Herty, H. T. Bogert and F. P. Garvan.

Water-Gas Production Costs

In a hearing before the Board of Public Utility Commissioners of New Jersey, Jan. 11, Henry D. Whitcomb, vice-president and general manager of the Public Service Gas Corporation, Newark, stated that a close estimate of the cost of production showed $0.5304 per 1,000 cu.ft. of gas in the Essex, Hudson and Bergen divisions of the system, and for all parts of the state in which the company operates, a figure of $0.5670 per 1,000 cu.ft. The company estimates unaccounted-for gas at 11 per cent.

U. S. Chamber of Commerce to Consider Metric System

Among the questions to be discussed at the meeting of the National Council of the Chamber of Commerce of the United States in Washington, Feb. 8 and 9, is a consideration of the advisability of legislation for the compulsory adoption of the metric system. At this time the special committee on metric system will make its report to the board of directors and the advantages and disadvantages of the adoption of the system will be presented.

The committee on railroads will also report to the directors and the railroad situation will be discussed.

Institute of Mining and Metallurgical Engineers Announces Program of 125th Meeting

The 125th meeting of the American Institute of Mining and Metallurgical Engineers will be held in New York, Feb. 20, 21, 22, 23, 1922. The first three days will be devoted to meetings of the various sections at the headquarters of the Institute, 29 West 39th Street.

Special entertainment has been arranged for evenings. On Monday evening, Feb. 20, a smoker will be held in the Engineering Societies Building. On Tuesday evening, two moving pictures, "Mexico and Its Oil" and "Through India With the Duke of Connaught, Including a Visit to the Tata Iron and Steel Works," will be shown. On Wednesday afternoon, Senator William A. Clark will open his art galleries to members and guests of the Institute. Admission tickets must be obtained at the registration desk. Wednesday evening will be devoted to the banquet.

The program of the meetings of the Institute of Metals Feb. 20 and 21 was given on page 86 of our issue for Jan. 11, 1922. Other papers of interest to our readers will be presented Wednesday, Feb. 22, in the Iron and Steel sessions.

Iron and Steel Session

10 a. m.—Room 1.

This session is in memory of Prof. J. W. Richards

Application in Rolling of Effects of Carbon, Phosphorus and Manganese on Mechanical Properties of Steel. By W. R. Webster.

Acid Open-Hearth Process for Manufacture of Gun Steels and Fine Steels. By W. P. Barba and Henry M. Howe.

Effect of Sulphur and Oxides in Ordnance Steels. By W. J. Priestley.

Electrolytic Deposition of Iron as Applied to Building Up Worn or Undersized Parts. By D. R. Kellogg.

2 p. m.—Room 2.

Effect of Time in Reheating Quenched Medium-Carbon Steel Below the Critical Range. By C. R. Hayward, D. M. MacNeil, and R. L. Presbrey.

Effect of Quality of Steel on Case-Carburizing Results. By H. W. McQuaid and E. W. Ehn.

Malleableizing White Cast Iron. By Arthur Phillips and E. S. Davenport.

Thursday will be devoted to excursions to several plants in New Jersey. The party will be divided into groups—those interested in steel, in oil and in copper. The members will ferry to Jersey City, where a special train will take the steel group to the plant of the Crucible Steel Co. of America, Harrison, N. J.; the oil group to the Bayway plant of the Standard Oil Co. (N. J.) and the copper group to the Chrome plant of the U. S. Metals Refining Co. About 2 hours will be allowed for seeing these plants. The special train will collect the different groups and take them to Perth Amboy, where they will be entertained at luncheon by the industries of Perth Amboy.

After luncheon the steel group will be given an opportunity to visit the Pardee Steel & Pardee Tile Works; the oil group the Chesebrough Mfg. Co. or the Barber Asphalt Co. and the copper group the Standard Underground Cable Co. or the Raritan Copper Works. The ladies of the party will be entertained at cards and tea during the afternoon. The groups will re-assemble at the Perth Amboy station about 4:30 p. m., for return by special train which will bring them back to New York about 5:30 p. m.

Present Status of Muscle Shoals Development —Investigation of Opposition Proposed

The report that Henry Ford has returned to the Secretary of War the contract for the lease of the Muscle Shoals water-power and nitrate plants with his signature attached presages the early consideration of the offer by Congress. Secretary Weeks has remained noncommittal as to the nature of the comment he will make in referring the proposal to Congress, but it is believed that his recommendations will carry considerable weight with the legislators. Senator Underwood has consistently maintained that the only way in which the public can obtain maximum benefit from the operation of the Muscle Shoals plants is by government operation. On the other hand, it is believed that the majority in the Senate favors a reasonable contract with responsible private interests, since government operation was blocked by the opposition of the ultra-conservationists to the formation of the proposed U. S. Fixed Nitrogen Corporation. It is expected that the proposal as it stands will be condemned by the fertilizer interests on the basis that Mr. Ford is obtaining property, in which the government has invested over eighty million dollars, at a ridiculously low figure—namely, five million dollars. Also, that in offering to pay 4 per cent on the construction cost of dam No. 2 the $15,278,828 already expended by the government has been disregarded. The point has also been raised that the granting of a 100-year lease with renewal option during that period is directly contrary to the Roosevelt water-power policy, adopted in 1920, providing for the recapture of water-power projects by the government at the end of 50 years. The Roosevelt policy also provides for the regulation of the price of power to the consumer and that public power taken for profit shall make a return to the public. Neither of these provisions is covered by the Ford contract as it stands.

On the other hand, there is undoubtedly a strong sentiment for immediate resumption of construction work on the dam among the agricultural interests and the advocates of industrial expansion in the South. There is little doubt that if Mr. Ford's plans materialize considerable industrial activity would be fostered by the abundance of water power available, although it is probable that only a relatively small part of the power developed by dams 2 and 3 would be used for the operation of the nitrate plants in the production of fertilizer.

Briefly stated, the Ford contract as far as made public at present provides for the completion of Wilson dam and the installation of hydro-electric equipment for the generation of 600,000 hp., the construction being undertaken by the Ford organization at cost. When completed, the company would pay to the government as annual rental of the property an amount equal to 4 per cent of the total cost of construction. The company would lease the dam, power house and all equipment for a period of 100 years. At the beginning of the seventh year and annually thereafter the company would pay to the government a sum not exceeding $39,537 to write off the cost of the dam, power house and appliances taken at $40,000,000—the sinking fund investments to bear the highest rate of interest obtainable but not less than 4 per cent per annum. The company would pay $35,000 annually for repairs and maintenance.

Upon the completion of dam No. 2 the government would construct dam No. 3 and its 250,000-hp. plant, the company to lease this property for 100 years, paying the government 6 per cent annually on the cost—taken at $8,000,000—except during the first 3 years after the plant is generating 80,000 hp., when the annual payments are $16,000, it being presumed that at the end of that period the plant will be complete and operating at full capacity. At the beginning of the fourth year of the lease period and annually thereafter the company would make amortization payments not greater than $7,010 to write off the cost of dam No. 3, taken at $8,000,000.

The actual purchase price of Nitrate Plants No. 1 and 2, including all equipment, patents and processes, the Waco quarry and equipment, the steam plant at Gorgas and transmission lines, is $5,000,000. The company would have the option of renewal of water-power lease and would guarantee to operate Nitrate Plant No. 2 to approximate capacity in the production of "nitrogen and other fertilizer compounds," the maximum net profit to the company not to exceed 8 per cent. Plant No. 2 would be maintained ready for the production of war materials and turned over to the government when required in the event of war.

Active opposition to the Ford proposal is led by the National Fertilizer Association, which has recently issued a chart as one of its Truth-About-Muscle-Shoals series, which shows that only 4c. of the "fertilizer" dollar goes for sulphate of ammonia. The intention is to emphasize the association's contention that no matter how cheap sulphate of ammonia is made at the Muscle Shoals plant, it could

not reduce the cost of fertilizer greatly. It is also pointed out graphically that it would cost $68 a ton to make sulphate of ammonia at Muscle Shoals, whereas the average wholesale price during 1921 was $48 per ton.

An investigation of the activities in opposition to the lease or other disposition of the government's plant at Muscle Shoals is provided in a resolution introduced in the Senate by Senator Harris of Georgia. A portion of the resolution reads as follows:

> Whereas it has been charged publicly that various persons, associations, corporations and combinations interested in the production of fertilizers, commonly known as the fertilizer trust, and various persons, associations, corporations and combinations interested in the production and transmission of power, commonly known as the water-power trust, have been and are engaged in extensive propaganda and in the maintenance of a lobby to defeat any plans for and to prevent the lease or other disposition by the government of the Muscle Shoals plant and projects; therefore, be it
>
> *Resolved*, That a committee composed of five Senators, to be appointed by the President of the Senate, is hereby authorized and directed to investigate such charges and activities of any such persons, associations, corporations or combinations, and to report its findings to the Senate with such recommendations as it deems proper.

Research on Motor Fuels Subject of Delaware Section, A.C.S., Meeting

"The Detonation of Gaseous Mixtures" was the subject of an address delivered by Thomas Midgley, Jr., chief engineer, Fuel Section of the General Motors Research Corporation, before the Delaware Section of the American Chemical Society in Wilmington on Jan. 16. "More miles per gallon" is a topic of almost universal interest, and the speaker explained that, as a result of his extended researches on the combustion of motor fuels, he could prescribe a never-failing method for producing the desired effect—namely, to decrease the clearance in the cylinder head and thus increase the pressure. This change always increases the power produced, but unfortunately it also causes severe "knocking."

During the study of various types of motor fuel, the speaker found that the ethers "knocked" at low pressures, then came the paraffines, olefines, aromatics and finally the alcohols, which would stand very high pressures without "knocking." Some blended motor fuels, such as benzene-gasoline-alcohol mixtures, appear to have some advantages over any one of their components used separately.

Mr. Midgley has studied a wide range of "anti-knock" compounds. Such materials as ethyl and phenyl chloride and iodide are effective, but are obviously impracticable on account of corrosion. The aromatic amines, such as aniline, toluidine, xylidine, etc., also prevent "knocking" if present to the amount of 2 to 3 per cent. The mileage of automobiles could be increased considerably by redesigning the motor to take care of motor fuels containing up to 10 per cent of aniline. The most effective "anti-knock" compound known was said to be tellurium-tetra-ethyl, but the available supply of tellurium is far from sufficient to treat the total amount of gasoline consumed.

"Chemical Education" Topic at South Jersey Section, A.C.S.

A symposium on "Chemical Education" was held by the South Jersey Section of the American Chemical Society on Jan. 19, at Carneys Point, N. J. Short papers were presented by P. W. Carleton, A. E. Houlehan, G. B. Bradshaw and W. S. Calcott, all of whom are members of the Jackson Laboratory or dyeworks staff of the du Pont company. The opinions expressed may be crystallized in the statement that the college and university training of a chemist should be merely a foundation and therefore should be as broad as possible. The general sentiment of the meeting was in favor of less industrial and applied chemistry and more thorough training in the proper use of the English language and mathematics in the modern college curriculum.

Personal

Charles A. Blaney has been elected president of the Eddy Paper Co, Kalamazoo, Mich., succeeding Oscar Gumbinsky, who recently tendered his resignation on account of other pressing business interests.

Robert M. Gates has resigned his position as engineer with the Lakewood Engineering Co., the resignation to be effective Feb. 1. Mr. Gates has made no definite plans for the future.

Chester H. Jones, Industrial Editor of Chemical & Metallurgical Engineering, stationed in Chicago, is in New York for a stay of a few days.

Charles W. Leavitt, consulting engineer for the Continental Asphalt & Petroleum Co., New York, is on an inspection trip to the company's properties in Oklahoma.

Dr. Lester A. Pratt, who has been in charge of the research laboratory of the Merrimac Chemical Co. for the past 6 years, has been made director of research for the same company.

Arthur W. Sewall, president of the General Asphalt Co., Philadelphia, Pa., has been elected a member of the board of directors of the Alliance Insurance Co. of that city.

Edgar C. Shimer, Allentown, Pa., has been re-elected president of the Brick Manufacturers' Association of Eastern Pennsylvania, Southern New Jersey and Delaware.

Dr. Ludwik Silberstein gave a lecture on "An Optical Experiment in Connection With the Rotation of the Earth," Jan. 26, 1922, at the Franklin Institute.

Harold B. Thorne, vice-president of the Metropolitan Trust Co., New York, has been elected vice-president and director of the Pierce Oil Co., New York. He will relinquish his position with the trust company at an early date, but will continue as a director and member of the executive committee.

Obituary

Dr. Charles Baskerville, director of the chemical laboratories of the College of the City of New York, died Saturday, Jan. 28, at his home, following an attack of pneumonia.

William H. Bradley, chief engineer of the Consolidated Gas Co., of New York, died recently of heart disease in his office. He had been chief engineer of the company 36 years. Although eighty-four years of age, he was a daily visitor to his office. He was born in New Haven, Conn., where he received a common school education, and for several years was employed in the mechanical department of a large manufacturing establishment. Shortly after his marriage at the age of twenty-one he entered the services of the Continental Iron Works in Brooklyn as a construction engineer. That company was then actively engaged in the execution of large government contracts, and among them, in 1862, was the building of Ericsson's *Monitor*, and Mr. Bradley took an active part in the building of that new war craft, which subsequently met and defeated the *Merrimac*. At the close of the war he went to Pennsylvania, where he established a plant to manufacture oil well drilling tools, returning to the Continental Iron Works as head of the gas department in 1870. Mr. Bradley became chief engineer of the Consolidated Gas Co. 2 years after its formation in 1884, and since then had made many valuable engineering contributions to the industry. The Astoria plant, the largest in the world, was constructed under plans and specifications drawn by him. Mr. Bradley leaves a widow, a daughter, Miss Bessie Bradley; two sons, George Bradley, assistant engineer of the Nevins street plant of the Brooklyn Union Gas Co., and Charles W. Bradley, gas engineer of the People's Gas, Light & Coke Co., in Chicago, Ill.

Market Conditions

IN CHEMICAL, METALLURGICAL AND ALLIED INDUSTRIES

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities—Prevailing Prices and Market Letters From Principal Industrial Centers

Business Conditions in January

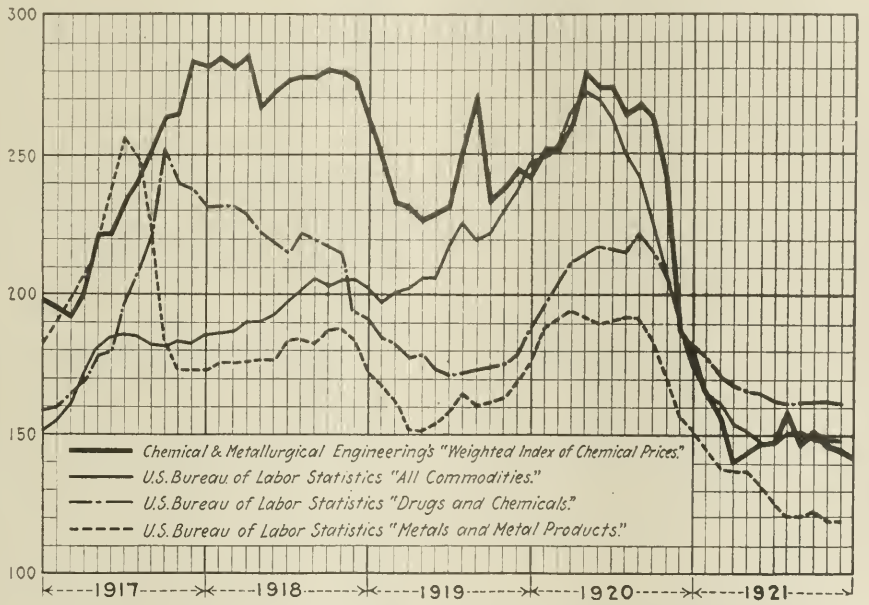
January contributed but little toward the improvement of fundamental conditions in business. Readjustment continued without interruption and without any particularly significant developments.

The full forces of depression were felt by practically every branch of business. Unemployment in the chemical, iron and steel and a number of other industries has been on the increase. Business failures, always most frequent during December and January, have occurred on an unprecedented scale. The greatest number of failures in 6 years was reported in 1921. Bradstreet's number reached 2,380 in December, which was the largest monthly total ever recorded. It is customary for January to show about one-fifth more business failures than December, so that another record-breaking month is to be expected. A significant factor in the general business situation has been the availability of credit at steadily declining rates of interest. In the first week of January time money dropped to 4¾ per cent and has since reached 4½ per cent. This is reported to be the lowest rate for this kind of a loan since August, 1917. Call money dropped to 3½ per cent on Jan. 6 and to 3 per cent on Jan. 9. On Jan. 16, however, the rate for call money jumped to 6 per cent and at the end of business on Jan. 26 stood at 4½ per cent. This is to be compared with 7 per cent of a year ago. A plentiful supply of credit means that working capital can be obtained with less difficulty and expense and should therefore react favorably on business.

Stocks and bonds have shown some improvement of late. The *Wall Street Journal* average for twenty industrials stood at 81.54 on Jan. 25, 1922, in comparison with a high of 81.50 and a low 63.90 for 1921.

The chemical market during January has been characterized by a continuation of the careful buying policies pursued by the consumers during the latter part of 1921. In spite of sharp price reductions there has been practically no real buying. What little demand exists has been for staples and other large-scale products rather than for specialties. Some long-time contracts have been recorded, but the number has doubtlessly been considerably less than is usual for the opening month of the year. Imports have continued to affect the market and have largely governed the prices of several important chemicals.

Price changes for particular commodities are reviewed in this week's letter on the New York market, and the general trend in chemical prices is reflected in the CHEM. & MET. index number. For the week ended Jan. 4 this index stood at 143.30, or 3.30 more than the 5-year minimum reported in April, 1921. On Jan. 11, it was 144.49; on Jan. 18, 143.75; on Jan. 25, 143.50, and on Feb. 1, 144.60. The average for the month of January was 144.09. The uncertainty regarding the tariff situation has had a very depressing effect on the chemical industry. The failure of the Senate to agree on a basis of valuation and Senator Smoot's prediction that the embargo on dyes would not be included in the new tariff law have discouraged trading and held production at a virtual standstill.



A COMPARISON OF WHOLESALE PRICES, 1917-1922

CHEMICAL & METALLURGICAL ENGINEERING'S WEIGHTED INDEX OF CHEMICAL PRICES

Base = 100 for the year July 1, 1913, to June 30, 1914

This week	144.60
Last week	143.50
February, 1921	166
February, 1920	252
April, 1918 (high)	286
April, 1921 (low)	140

There was a noticeable increase in the index number during the past week due principally to the higher prices for vegetable oils. Linseed oil advanced 4 cents on the gallon and cottonseed oil was up ¼ cent per pound. The lower prices for caustic soda, methanol and formaldehyde failed to offset the upward movement of the index.

Wholesale Prices, 1917-1922

A graphic comparison of the prices for chemical and metallurgical products with the general average for all commodities is afforded by the accompaning chart. It is of interest to note the close relation which has existed since 1919 between the CHEM. & MET. index of chemical prices and the Department of Labor's average for over 300 commodities. These curves exhibit the same general tendencies, although there is an apparent lag of 1 to 3 months in the case of the chemical prices. Both reached the 1920 maximum in the month of April.

The indexes for metal products and drugs and chemicals also show a certain noticeable similarity. During 1919 and 1920 both were considerably under the average for all commodities. Since December, 1920, the Labor Department's index for drugs and chemicals has been 10 to 15 per cent above the general level, while on the other hand, metals and metal products have been 20 to 30 per cent under this average.

Decreased Output of Cottonseed Oil

Figures recently issued by the Bureau of the Census show that the production of crude cottonseed oil during the last 5 months of 1921 was about 5 per cent less than during the same period in 1920 The principal cottonseed products manufactured, shipped and in stock are shown in the following table:

	Year	On Hand Aug. 1	Produced Aug. 1 to Dec. 31	Shipped Out Aug. 1 to Dec. 31	On Hand Dec. 31
Crude oil, lb....	1921	*18,762,794	611,412,655	545,846,505	*100,167,166
	1920	22,620,357	643,566,331	543,037,678	156,088,844
Refined oil, lb...	1921	†228,263,633	‡461,488,151	.....	†257,577,703
	1920	297,741,580	445,926,305	.....	274,388,802
Cake and meal, tons.....	1921	36,303	900,545	679,410	257,437
	1920	133,475	897,787	787,080	244,182

* Includes 4,346,848 and 9,315,790 lb. held by refining and manufacturing establishments and 5,507,880 and 16,377,160 lb. in transit to refiners and consumers Aug. 1 and Dec. 31, respectively.

† Includes 5,884,495 and 9,638,605 lb. held by refiners, brokers, agents and warehousemen at places other than refineries and manufacturing establishments and 7,969,713 and 6,202,928 lb. in transit to manufacturers of lard substitute, oleomargarine, soap, etc., Aug. 1 and Dec. 31, respectively.

‡ Produced from 501,376,842 lb. crude oil.

Savings Resulting From Standardization

An intelligent program of standardization has been urged by the Department of Commerce because of the many ways in which it will benefit the manufacturer, distributor and consumer. Some of the direct gains to the manufacturer have been listed by the Fabricated Production Department of the Chamber of Commerce. Among those which apply to chemical manufacturers and dealers are included the following:

Gains to Manufacturers

1. Less capital tied up in
   - *a* Raw materials.
   - *b* Semi-finished stock.
   - *c* Finished stock.
   - *d* Manufacturing equipment.
2. More economical manufacturing through
   - *a* Larger production units.
   - *b* Longer runs.
   - *c* Simplified inspection.
   - *d* Cheaper handling of materials and stock.
   - *e* Simplified cost methods.
3. Increased efficiency of labor by
   - *a* Making personnel training more simple.
   - *b* More permanent employment.
4. Better service to trade in
   - *a* Controlling quality of product.
   - *b* Prompt delivery.
   - *c* Standardized packing.
5. More efficient sales force.
6. Fewer factory shutdowns.

Gains to Dealers

Those who handle chemical products in the wholesale markets might profit in the following ways:

1. Increased rate of turnover due to
   - *a* Elimination of slow-moving stock.
   - *b* Concentration of sales on fewer items.
2. Decreased capital invested in
   - *a* Stocks.
   - *b* Storage space.
3. Less stock depreciation and obsolescence.
4. Decreased overhead.
5. Better service to consumers.

General Asphalt Co. Shows Large Deficit

The forthcoming annual report of the General Asphalt Co. is expected to show a loss of about $1,000,000 for 1921. Although about half of this deficit is accounted for by arbitrary charges to depreciation and reserve accounts, the company has been severely affected by adverse business conditions and the fire at the Maurer, N. J., plant.

Since such unusual conditions cannot be expected to occur again, the directors of the company have seen no reason to discontinue payment of the preferred dividends and last week declared the regular quarterly dividend, payable March 1. The loss incurred in 1921 can easily be absorbed, since the profit and loss surplus at the close of 1920 amounted to over $5,000,000.

The officials of the company are more optimistic regarding business for the current year. New contracts, the resumption of road-building by states and municipalities and the promising increase in building activity are all regarded as favorable factors.

The new plant erected at Maurer, N. J., at a cost of about $3,000,000 was completed late in 1921 and has not yet had time to demonstrate the savings which will result from its greater efficiency and more modern equipment.

Industrial Reconstruction in France

The French Office for Industrial Reconstruction of the Liberated Regions has prepared a table showing the relation between productive capacity in the devastated regions at the present time and that which existed prior to the war. The percentages given for some of the principal industries are as follows:

	Production Compared With 1914 Per Cent	Labor Compared With 1914 Per Cent
Iron and steel	50	55
Other metallurgy	66	63
Chemical industries	58.5	62
Hides and leather	45	67
Textiles	53	55
Cothing	58.5	73
Mlining	31	36

The average for all industries would appear to be about one-half of the pre-war production, but it is stated that not all of the productive capacity is effective because of the present economic crisis.

Extra Dividend by Dow Company

The Dow Chemical Co. of Midland, Mich., has declared an extra dividend of 1¾ per cent on the common stock in addition to the regular quarterly dividend of the same amount. The regular quarterly dividend on the preferred stock was also declared. All dividends are payable Feb. 15 to stock of record Feb. 4.

The New York Market During January

NEW YORK, Jan. 30, 1922.

The chemical market during the past month has been something of a disappointment to those who had expected a radical improvement to follow the opening of the new year. There are a few indications, however, that the industry has been moving along the line of a gradual but rather general development. Among the outstanding features of the commodity market during January has been the steady decline in the prices of caustic soda, soda ash and the alkalis in general. However, the belief is quite commonly expressed that the bottom has been reached. The consumers have shown more attention to contracts during the past month and considerable business has been booked with the glass-making, soap and textile industries. It has been estimated that as much as 75 per cent of the regular consuming trade for alkali products is now covered by 1922 contracts.

The pronounced activity and steady demand for the prussiates has continued all during January. Yellow prussiate of potash opened at 24c. per lb. and is practically nominal on spot at about 25c. per lb. The red variety has made greater strides with a quoted advance of 3c. per lb. at the close of the month.

Another item that has been of market interest is arsenic. Leading importers who have received regular shipments from abroad have found it practically impossible to book any forward shipments for round quantities. Domestic producers are not anxious to quote at present prices, claiming the profits are too small. Opinion among large smelters is that arsenic will reach 10c. per lb. before the spring season. The opening quotation for 1922 was 6c. per lb., with a closing figure for the month of January around 7½@8c.

Linseed oil has been another commodity to show a sharp increase during the month. Opening the year at 67c. per gal. for carlots, prices reached 74c. during the past week and the market continues to be firm.

Developments of the Week

Among the developments of the week has been a decline in the spot price of caustic soda. The lower prices were due to the falling off in export orders and the producers' desires to attract additional buyers. Considerable business was recently booked to Japan, Italy and South America. Business to the Orient was seriously restricted recently by increased freight rates. Sales for export were recorded at $3.60 per 100 lb. Dealers reported a quiet movement in resale caustic at $3.50@$3.60 per 100 lb. Goods ex-store in small lots have sold up to 3¾c. per lb. Producers still maintain prices at $2.60 per 100 lb., basis 60 per cent, f.o.b. works. Exports of soda ash have been small since the beginning of the year due to English and German competition. Light ash, single bags, is moving at $1.75@$1.85 per 100 lb., depending upon the seller and quantity. Dealers are quoting barrels at $2@$2.15 per 100 lb. and report a fair movement. Producers' quotations remain at $1.35 per 100 lb. in bags and $1.55 in barrels, f.o.b. works, basis 48 per cent. Dense ash is being bought by the glass industry at 10c. per 100 lb. higher. Bichromate of soda has shown more activity of late and the market appeared steadier since the recent decline. Tanneries are inclined to buy only for immediate consumption. Prominent sellers quote 7¾c.@ 8c. per lb. on spot and the same figures were named for forward shipments. Some large contract sales have gone through for delivery over the year. Producers have reduced prices on chlorate of potash to 8c. per lb. for immediate or forward deliveries, f.o.b. works. Second hands are asking 5¾@6c. per lb. for spot imported chlorate and state that business is very quiet. Makers of formaldehyde have lowered their quotations to 10c. per lb. in barrels. This is a new low price for this chemical. Dealers generally quote the market around 10½c. per lb. for odd lots. Nickel salts are down to 11c. per lb. for both the double and single varieties. Manufacturers of cream of tartar have announced another sharp reduction and now quote 21½c. per lb. for the crystals and powdered U. S. P. Imported material is somewhat weaker on spot and sellers are openly quoting 23c. per lb. Owing to competition from the imported material, domestic makers of tartaric acid have again reduced prices and now quote 30c. per lb. Imported U. S. P. is still held at 25@26c. per lb. The prussiate of potash market is very strong and spot stocks of the red or yellow are difficult to locate. The red variety is nominally quoted at 33@34c. per lb. The yellow is held at 25@26c. Arsenic prices are very firm and makers quote 7½c. per lb. for limited amounts. The consuming demand is holding steady. Manufacturers of barium chloride sold several carlots early in the week at $50 per ton, but have retracted their figure and now quote $52 as the minimum. Importers are experiencing great difficulty in competing with American producers and ask $53 per ton for limited amounts. Prices range all the way up to $70 per ton, according to quantity and seller.

The Metal Markets

The New York metal markets have been exceedingly dull during January, and no immediate improvement is being anticipated by leading interests. Metal products will probably not experience any marked price recessions in the next few months, but all indications are that the gradual improvement which took place around the closing months of 1921 is practically at an end. Most of the large producers of copper are quoting 14c. delivered but there are few buyers at this price. Resale merchants are doing a fair business at 13¾c. on spot and second quarter delivery. The copper market on the whole was noticeably weaker owing to the fact that producers have announced the reopening of some mines and the expected early resumption of others. This has caused consumers to wait in the hope that competition would drive prices down to a lower level. The official lead price remains at 4.70c. Leading producers reported an unusually quiet week with an occasional sale noted here and there. The London price has recently declined owing to increased shipments from Australia and the possibility of imports from United States. The market on zinc continued its decline, with sales fewer and smaller in volume. The price earlier in the week was held at 4.70c. but has dropped since to 4.60c.

The Chicago Market

Chicago, Jan. 27, 1922.

Developments were lacking in the industrial chemical market during the past two weeks. A few items are showing an indication of strength, but for the greater part the list is dull and neglected. The tendency to shade prices on the part of weak holders is again in evidence, but this is having little if any disturbing effect on the market. Price reductions have proceeded to a point where it cannot be expected that further sharp reductions will be named in the near future. There are many items on the list which are now priced either at or below the pre-war levels and on the whole the prices existing at the moment are not so far from those prevailing in 1914.

General Chemicals

The alkalis are weak on spot and very little material is moving in consuming channels. Holders have announced no reductions in their schedules and are offering solid caustic soda 76 per cent at $3.75 per 100 lb. The ground 76 per cent is quoted at $4.50. It is very possible that with a firm order in view these prices would be shaded. Caustic potash is quiet and firm at 6½c. per lb. for the 88-92 per cent material. Soda ash is quoted lower by some holders and $2.30 per 100 lb. for 58 per cent material in cooperage could readily be obtained.

Potash alum is quiet, with imported lumps available at 5½@6c. per lb. and the powdered at 6@6½c. White arsenic is one of the firmest items on the list and 8c. was apparently rock bottom for spot goods. Barium chloride is in but little demand and imported white crystals are quoted at $60 per ton. Blue vitriol is moving in a fair way and is unchanged at 6c. per lb. Carbon bisulphide is quiet, with supplies available at 7@7½c. per lb. Glycerine is among the strong items and is very firm at 16½@17c. per lb. for the c.p. grade in drums.

The bichromates are moving in a routine way and apparently ample supplies are available. Potash bichromate was offered at 11¾c., which is a somewhat lower figure than has been named lately. Sodium bichromate is very firm at 9@9½c. per lb. for material of standard brand. Red prussiate of potash is very scarce and material under 34c. per lb. could not be located. Potassium permanganate was in limited request and could be had at 17c. per lb. for U.S.P. crystals. Sodium fluoride is quiet and unchanged as to price at 11@12c. per lb., according to quantity and holder. Sodium hyposulphite is quoted lower by makers, the new level for pea crystals being $3.95 per 100 lb. for single barrels.

Vegetable Oils

Linseed oil is reported to be moving very slowly to the consuming trade but fairly well to speculators. The boiled oil was offered today in 10-bbl. lots at 81c. per gal. and corresponding quantities of the raw at 79c.

Naval Stores

Turpentine is in but a very limited demand and no sales of consequence were reported today. Ten-drum lots were quoted at 92c. per gal., delivered. Rosins were reported to be moving well in carlots, but very slow in 1- or 2-bbl. quantities. The WW grade was quoted today at $9.30 per 280 lb. in less than carlots.

The Iron and Steel Market

Pittsburgh, Jan. 27, 1922.

It may be that the current demand for steel products is no lighter than the demand of a month ago, and it may even be that on the whole the demand is a trifle heavier, but it is quite certain that the situation is decidedly unsatisfactory and disappointing. There was universal expectation that January would show a very decided improvement in demand, not necessarily a new high rate on this movement, which began after the extreme depression of early July, but an improvement over the December showing, as December witnessed a distinct lull as compared with conditions in the 2 months preceding. Such expectation has been

disappointed. January is little if any better than December and it is not nearly as good as November or October.

Expressed in tonnage rate of production, which may be estimated roughly for the present time and is known fairly well for previous months, production of steel ingots now is at a rate of about 18,000,000 or 19,000,000 tons a year. This is to be compared with a rate of 23,000,000 tons in October and November and a rate of 20,000,000 tons in December, the rate at the close of December being lower, perhaps 18,000,000 tons.

No precise and satisfactory explanation of the condition of demand is obtainable. Reference to buyers being disposed to buy "from hand to mouth" is not explanatory, since there has been no time recently when buyers were in any other mood. There is no disclosed change in fundamental conditions that would make for lighter consumption of steel. Possibly the explanation is simply that actual ultimate consumption of steel always decreases in midwinter and that ordinarily the decline is covered up by mills and their customers being supplied with orders for extended delivery, so that they have momentum to carry them over the lull.

Prices Unsteady

The unsatisfactory condition of the steel market is not due alone to the volume of demand being light by comparison with conditions of 2 or 3 months ago. There is a weakness in prices that is decidedly menacing. The regular or asking prices are unchanged on the leading mill products, but concessions from these prices are much more common. Recently it required a good-sized tonnage to be offered to draw a price concession, whereas now concessions in the case of several products are made on relatively small orders. In some lines the regular prices scarcely obtain on orders for anything beyond carloads, and in the case of bars orders for less than carload lots go at what is considered the regular market, 1.50c.

Perhaps the clearest analysis of the situation is that the mills have got themselves into a tangle in their keenness to meet the situation and encourage distributors and consumers to go ahead. There is one cost per ton when a mill is running at one rate and another cost when it is running at another rate. In the effort to get a larger operation and thus reduce costs mills have given price concessions in keeping with the larger operation expected and have failed to get the higher operating rate, so in the effort to avoid losing money they may lose more money.

The market cannot proceed indefinitely on its present basis. Unless demand broadens it is quite probable that some mills will drop out of the competition. Demand, however, is certain to improve with the approach of spring.

Regular prices, which in some cases obtain only on relatively small lots, remain as follows: Bars, shapes and plates, 1.50c.; standard steel pipe, 71 per cent basing discount; plain wire, 2.25c.; wire nails, $2.50; blue annealed sheets, 2.25c.; black sheets, 3c.; galvanized sheets, 4c.; tin plate, $4.75. The sheet prices are maintained absolutely, so far as can be observed. The tin plate price is maintained as well as is usually the case. In wire products the chief weakness is that some districts have local markets of their own, having departed from Pittsburgh basing. Hoops are easier, 1.90c. being done sometimes instead of 2c. while hot-rolled strip has gone as low as 1.75c.

Pig Iron and Coke

A lot of 1,000 tons of basic pig iron has been bought by a Pittsburgh consumer at a delivered price equivalent to $17.75 valley, but this was resale iron, sold by a middleman, and does not make the market. On the inquiry valley furnaces quoted $18 valley, against the former nominal market of $18.25. Foundry iron is off 50c., the Standard Sanitary Manufacturing Co. having bought 500 tons from each of two valley producers at $19. Bessemer is unchanged. The market is now quotable at $19.50 for bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces, freight to Pittsburgh being $1.96.

Connellsville coke for spot shipment continues soft, with furnace coke obtainable in small lots at $2.75 and foundry ranging from $3.75@$4.25.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

PYRITON—John Boyd, R.F.D. No. 2, and associates are planning for the establishment of a new local plant for the production of commercial mica. Grinding and other machinery will be installed.

TUSCALOOSA—Officials of the local Chamber of Commerce are considering the establishment of a brick-manufacturing and clay-working plant. A company will be organized to operate the works.

California

LONG BEACH—The Long Beach Milling Co., 1058 Appleton St., has disposed of its plant site and plans for the erection of a new flour mill on property recently acquired on Willowville Ave., near American Ave., 300 x 300 ft. The new plant will include a number of work buildings in addition to the main mill. E. I. Harnett is president.

Connecticut

MIDDLETOWN—The Mohawk Mfg. Co., Waterbury, manufacturer of brass products, has purchased the factory of W. E. Stroud on College St., 50 x 100 ft., and will equip the structure for a new plant. Later an addition will be constructed.

Florida

MIAMI—The Dixie Rubber Co., Memphis, Tenn., is considering the erection of a new branch plant at Miami, estimated to cost about $250,000, including machinery. L. C. Cadenhead is president.

CANAL POINT—The Florida Sugar & Food Products Co. is planning for the early occupancy and operation of its new local plant building, designed to increase the sugar mill output by about 400 tons a day.

Georgia

SAVANNAH—The Gulf Refining Co., Port Arthur, Tex., is planning for the construction of a new oil storage and distributing plant on Hutchinson Island, near Savannah, with capacity of about 55,000 bbl., doubling the present facilities. The work is estimated to cost about $100,000.

Illinois

CHICAGO—The Garden City Paint & Varnish Co., Troy and 25th Sts., has awarded a contract to Frederick Marz, 1515 South Austin Ave., for the erection of a 2-story top addition to its plant, 52 x 75 ft. Work will be commenced at an early date.

CHICAGO—The Niagara Radiator & Boiler Co., Tonawanda, N. Y., has construction well under way on a new foundry at 1101-13 East 83rd St., Chicago, and will occupy the structure at an early date. It will be 1-story, 130 x 400 ft., with other departments devoted to machine shop operations.

Indiana

MUNCIE—The Ball Brothers Mfg. Co., manufacturer of glass jars, etc., has broken ground for the erection of a new 2-story plant addition, 90 x 300 ft., to cost about $100,000. A portion of the structure will be used for general manufacturing and the remainder for storage purposes. A. Kibele, Johnson Bldg., is architect.

JONESBORO—The Indiana Rubber Co., First and Pearl Sts., will take bids early in the spring for the erection of its proposed 3-story plant addition, 60 x 125 ft. Plans have been drawn.

HUNTINGTON—The Huntington Chemical Co. is planning for the installation of new extraction and other equipment at its plant. A bond issue will be arranged to provide funds for the improvement. Fred H. Bowers is president, and J. L. Brenn, secretary.

Louisiana

ALEXANDRIA—The Adam Brick Co., recently organized with a capital of $50,000, has acquired the local plant of C. N. Adams, and in the future will operate the property. J. H. Johnson is president and W. D. Hill, secretary and treasurer.

Maryland

BALTIMORE — The Spanish-American Cork Products Co., Westport, near Baltimore, is planning to call for bids early in the spring for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about $40,000. Plans will be prepared at once. O. J. Harms is president.

Massachusetts

WALPOLE—Bird & Son, Inc., manufacturer of prepared paper roofing, has awarded a contract to the M. W. Allen Construction Co., Walpole, for the erection of a 1-story addition, to be used as a paper machine department.

Missouri

JOPLIN—The Joplin Zinc Products Co., will take bids during February for the construction of a new rolling mill. It is planned also to construct a plant for the manufacture of zinc roofing shingles. R. E. Love, 1531 East 7th St., Joplin, is architect.

KANSAS CITY—The Barnsdall Refining Co. has plans under way for extensions to the blending plant at its local oil refinery, formerly operated by the Plains Oil Co.

New Hampshire

NEWINGTON—Fire, Jan. 16, caused by an explosion, destroyed a portion of the plant of the Atlantic Dyestuffs Co., including equipment, chemicals, etc. The greatest damage was done to Bldg. No. 2. An official estimate of loss has not been made.

New Jersey

BOGOTA—The Bogota Paper & Board Co. will commence the immediate erection of a new 1-story mill addition. A power house will also be constructed. The work is estimated to cost about $42,000. Contract for the buildings has been let to the Austin Co., 217 Broadway, New York, N. Y.

NEWARK—The Orbis Products Trading Co., Wyckoff Ave., Brooklyn, N. Y., manufacturer of chemicals, oils, etc., has acquired property on Frelinghuysen Ave., extending to Virginia St., Newark, totaling about 4 acres, for the erection of a new plant. The works will consist of a series of buildings, and will be used for the distillation of essential oils and chemicals, the installation to comprise a number of mills for the grinding of gums and drugs, and auxiliary machinery. The entire plot will be utilized for the plant, plans for which will be placed under way at once.

WOODSTOWN—The South Jersey Farmers' Exchange is planning for the rebuilding of its fertilizer works, recently destroyed by fire with loss estimated at close to $150,000. Asa Moore, Mullica Hill, N. J., is president.

NEW BRUNSWICK—The Atriken Chemical Works, New Brunswick, N. J., have leased three 1-story buildings, forming part of the plant of the Hewes & Phillips Iron Works, recently dissolved, at 12-22 Orange St., Newark, and will remove its present plant to this location. Possession will be taken at once and necessary remodeling placed under way.

JERSEY CITY—The Baker Castor Oil Co., Bay St., has filed plans for the erection of a new 2-story plant at 80 Morgan St., estimated to cost about $25,000. Work will be commenced at once.

BRIDGETON—The Cumberland Glass Mfg. Co., manufacturer of glass bottles, jars, etc., has awarded a contract to Keeley Bros., Bridgeton, for the construction of a new plant on Laurel St., consisting of a number of 1-story buildings, estimated to cost in excess of $1,000,000, including machinery.

KEARNY—The plant of the Stern Rendering Co., River Rd., was destroyed by fire Jan. 19, with loss estimated at about $300,000, including buildings equipment, etc. Louis Stern is head.

New York

LONG ISLAND CITY—The Egan & Hausman Co., Inc., 476 Clinton Ave., Brooklyn, manufacturer of colors, etc., has awarded a contract to Levering & Garrigues Co., 552 West 23rd St., for the erection of a new 2-story plant, 50 x 100 ft., at Bodine and Hamilton Sts., Long Island City, estimated to cost about $25,000. Work will be commenced at once.

NEW YORK—The Hydro-Bar Waterproofing Co. has acquired the 3-story building at 356 First Ave., now occupied, and the adjoining 4-story building at 404 East 21st St., for expansion.

NEW YORK—The Chile Copper Co., 120 Broadway, has preliminary plans under consideration for extensions in its plant to increase the output from 15,000 to 35,000 tons a day. The work will be commenced as soon as conditions warrant.

North Carolina

GREENSBORO—The Pomona Terra Cotta Co., has commenced the erection of a new factory, to be known as Plant No. 4. It will consist of a number of buildings, with main structure, 70 x 225 ft. Other structures will approximate 30 x 50 ft. A total of 8 new kilns will be installed at the plant, each about 36 ft. in diameter. W. C. Boren, Jr. is secretary and treasurer.

ALBEMARLE—The City Council is having plans prepared for enlargements in the filtration plant at the municipal waterworks. Gilbert C. White, Durham, N. C., is consulting engineer.

WINSTON-SALEM—George D. Hodgin, Winston-Salem, is planning for the construction of a new brick- and tile-manufacturing plant on site now owned at Daisy, near Winston-Salem.

Ohio

WARREN—The K. W. Brick Co., 607 Home Savings & Loan Bldg., Youngstown, O., will soon commence the erection of a new brick manufacturing plant at Warren, to be 1- and 2-story, 70 x 150 ft., and estimated to cost about $30,000. J. Whittaker is president.

Oklahoma

OKLAHOMA CITY—The Process Refining Co., recently organized with headquarters at Oklahoma City, has acquired the plant of the Pirtle-Pittman Refining Co., at Newkirk, Okla. A number of improvements will be made to the refinery, including the installation of a new refinery process. A. C. Heiden is vice-president; and C. H. Hyde, secretary and treasurer.

HENRYETTA—The Harper Oil & Refining Co., recently incorporated with a capital of $200,000, has commenced excavations for a new oil refinery, on property purchased in the southwestern section of the city. A 10-acre tract of land has been secured for the plant, which will have an initial capacity of about 1,000 bbl. per day. J. P. Harper is president, and E. D. Ham, secretary.

ARDMORE—The Choctaw Oil & Milling Co. is said to be planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated at about $40,000.

Pennsylvania

OIL CITY—The Oil Well Supply Co. will install a large electric steel furnace in one of the new buildings now being erected at the plant.

PHILADELPHIA—The Glenwood Industrial Distilling Co. has taken title to the 1-story and basement building on Cedar St., near Tioga St., and will use the property for a local works. It was obtained for a consideration said to be $38,000.

PITTSBURGH—Bethlehem Laboratories, Inc., a $5,000,000 corporation, has been organized here to manufacture a new antiseptic known as Hyclorite, possessing 175 times germicidal strength of hydrogen peroxide. Among incorporators are Homer D. Williams, president of Carnegie Steel; Taylor Allerdice, vice-president of National Tube; and Dr. J. J. Reilly, surgeon, United States Shipping Board. Plans include construction of modern chemical plant here.

Rhode Island

CRANSTON—Fire recently destroyed a portion of the local plant of the Graphite Mines Corp., with loss estimated at about $100,000, including buildings, equipment and stock.

Tennessee

DAYTON—The Dixie Coal, Lime & Clay Products Co., recently organized with a capital of $750,000, O. E. Thomas, Dayton,

president, has plans under way for the erection of a large brick- and tile-manufacturing plant at Graysville, eastern Tennessee district, where extensive propery has been secured. The initial works will have a capacity of 50,000 bricks per day, with departments for tile and stoneware manufacture. The company is planning also for the construction of a hydrated lime-producing plant, with initial capacity of about 50 tons daily.

Texas

THREE RIVERS—J. E. Jarrett and C. H. Kearney, Three Rivers, are organizing a company for the construction and operation of a local plant for the manufacture of glass products. Plans will be prepared at an early date.

LAREDO—The Kirk Refinery Co., San Antonio, has construction under way on a new plant at Laredo, for the manufacture of lubricating oils. The company has secured a site near the shops of the Texas-Mexican Railway Co. The refinery will have an initial output of about 1,200 bbl. per day, and will handle crude oil from the Mirando oilfield. E. W. Kirkland, San Antonio, is president; and R. B. Thomas, Tulsa, Okla., secretary and treasurer.

DALLAS—The Davis Mfg. Co., Knoxville, Tenn., manufacturer of chemical products, has completed plans for the erection of a new branch plant at Dallas, to be 3-story, and estimated to cost about $50,000. Contract will be let and the work commenced at an early date. Grover C. Davis is president and general manager.

YOAKUM—The Texas Hide & Leather Co., is planning for the erection of an addition to its plant for sole leather and other leather manufacture. The company is arranging for an increase in capitalization to $200,000. J. B. Harris is manager.

Washington

SPOKANE—The Bentley Paste Co., Minneapolis, Minn., has commenced work on a new branch plant at Spokane, for the manufacture of paste and kindred products. It will be ready for service at an early date.

West Virginia

NITRO—The Rubber Service Laboratories Co., Akron, O., has acquired a site at Nitro, for the construction of a new plant for the manufacture of chemical and affiliated products, to be used in connection with rubber vulcanizing work. Carl N. Hand, Nitro, is local representative for the company.

New Companies

THE K. S. T. NOVELTY CO., New York, N. Y., has been incorporated with a capital of $400,000, to manufacture celluloid and composition products. The incorporators are M. Grehman and I. Siper. The company is represented by J. G. Kremer, 233 Broadway, New York.

KNELLER, VAUGHN & CO., INC., New Haven, Conn., has been incorporated with a capital of $50,000, to manufacture liquid metal cleaners and other chemical products. The incorporators are Charles S. Vaughn, Henry S. Kneller and Frank H. Kasperson, 332 Norton St., New Haven.

THE HARBOR PRODUCTS CO., Carlstadt, N. J., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are J. F. C. Grow, H. G. Boardman and Frederick L. Locke, Carlstadt.

THE M. S. CHEMICAL CO., 1131 Stevens Bldg., Chicago, Ill., has been incorporated with a capital of $50,000, to manufacture carbon removers, cleansers and other chemical products. The incorporators are Milton L Smith, Norman H. Pritchard and William P. McCracken, Jr.

THE GULF & REFINERS' CORP., New York, N. Y., has been incorporated under Delaware laws with capital of $1,000,000, to manufacture petroleum products. The company is represented by the United States Corporation Co., 65 Cedar St., New York

THE SAN-NOX CHEMICAL CO., Birmingham, Ala., has been organized under state laws to manufacture chemicals and chemical byproducts. James Johnson is president; J. G. Dickinson, vice-president; and H. H. Smithcon, secretary and treasurer, all of Birmingham.

THE BRUCE MARVIN CHEMICAL CO., Boston, Mass., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. Joseph A. Conway is president, and Joseph J Crotty, 185 Columbus Ave., Boston, treasurer.

THE F. E. M. MFG. CO., New York, N. Y. has been incorporated with a capital of $10,000, to manufacture chemicals and affiliated products. The incorporators are J. Baker, J. Levy and I. Kaplan. The company is represented by A. E. Schwartz, 140 West 42nd St., New York.

THE ILLINDA OIL CO., Breckenridge, Tex., has been incorporated with a capital of $350,000, to manufacture petroleum products. The incorporators are G. E. Stocking, W. E. Bowler and Fred Phipps, all of Breckenridge.

THE UNIVERSAL CHEMICAL CO., Wilmington, Del., has been incorporated under state laws with capital of $1,000,000, to manufacture chemicals and chemical byproducts. The company is represented by the Corporation Trust Co. of America, du Pont Bldg., Wilmington.

THE BAYONNE STEEL PRODUCTS CO., Bayonne, N. J., has been incorporated with a capital of $250,000, to manufacture steel and other metal products. The incorporators are Harry B. and Charles H. Dembe, 216 Jelliff Ave., Newark, N. J.

THE JAMES H. COOPER CO., INC., Westborough, Mass., has been incorporated with a capital of $50,000, to manufacture leather products. James R. Cooper, 11 Beach St., Westborough, is treasurer.

THE CONTINENTAL CERAMICS CORP., New York, N. Y., has been incorporated with a capital of $10,000, to manufacture pottery and other ceramic products. The incorporators are W. S. McKay, L. E. Hellman and V. I. Weldon. The same incorporators have also formed the ROSENTHAL CHINA CORP., with capital of $10,000, to manufacture and deal in chinaware. Both companies are represented by S. F. Hartman, 120 Broadway, New York.

THE SAVANNAH CHEMICAL CO., Savannah, Ga., has been incorporated under state laws to manufacture chemicals and chemical byproducts. The incorporators are George L. Groover and W. B. Stratford, both of Savannah.

THE SEA LEATHER & OIL CORP., Caldwell, N. J., has been incorporated under Delaware laws with capital of $6,300,000, to manufacture leather products, oils and affiliated specialties. The incorporators are Frank C. Myers, Caldwell; Charles W. Owen, Hackensack, N. J.; and Robert Strange, Orange, N. J. The company is represented by the United States Corporation Co., 65 Cedar St., New York, N. Y.

THE NEWTON CHEMICAL CO., Newton, Mass., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. Charles G. Pickett is president; and William Hahn, Newton Centre, Mass., treasurer.

THE CARBON DIOXIDE PLANT FOOD CO., St. Augustine, Fla., has been organized under state laws to manufacture fertilizer products. W. B. Guy is president; Robert Ranson, vice-president; and R. D. Crawley, secretary and treasurer, all of St. Augustine.

IRELAND & HOLMES, INC., New York, N. Y., has been incorporated with a capital of $20,000, to manufacture pulp and paper products. The incorporators are W. H. Holmes, C. H. Ireland and K. C. Newman, 38 Park Row, New York.

THE AMERICAN OIL CO., fourteenth floor, American Bldg., Baltimore, Md., has been incorporated with a capital of $2,250,000, to manufacture petroleum products. The incorporators are Louis and Jacob Blaustein, and Alvin Thalheimer.

THE CALCO CHEMICAL CO., New York, N. Y., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are R. C. Jeffcott, G. A. Berry and W. G. Heath. The company is represented by S. C. Morehouse, attorney, New Haven, Conn.

THE EVANSVILLE PAINT & VARNISH CO., Evansville, Ind., has been incorporated with a capital of $50,000, to manufacture paints, varnish, etc. The incorporators are H. D. Bourland, Arthur C. Heberer and E. L. Fowler, all of Evansville.

THE PLYMOUTH RUBBER CO., Canton, Mass., has been incorporated with a capital of $150,000, to manufacture rubber products. Maurice J. Hamilburg is president; and Reuben B. Gryzmish, 70 Marshall St., Boston, treasurer.

THE NO RUB AUTO POLISH CO., Newark, N. J., has filed notice of organization to manufacture polishes and other chemical products. Joseph Lardiere, 132 Summer Ave., heads the company.

THE FRIENDS OIL CO., Wilmington, Del., has been incorporated under state laws with capital of $100,000, to manufacture petroleum products. The company is represented by the Corporation Service Co., Wilmington.

Capital Increases, etc.

THE TIDAL OSAGE OIL CO., Tulsa, Okla., has filed notice of increase in capital from $52,000,000 to $102,000,000.

THE MATTHIESSEN & HEGELER ZINC CO., La Salle, Ill., has filed notice of a reduction in capitalization from $426,000 to $310,000.

THE EASTERN MFG. CO., Lincoln, Me., manufacturer of bleached sulphite pulp and paper products, has disposed of a bond issue of $2,500,000, for financing, general operations, etc. Stuart W. Webb is chairman of the board.

THE TODD SALT CO., 409 East 8th St., New York, N. Y., has filed notice of increase in capital to $40,000.

THE HAWK OIL CO., Tulsa, Okla., has filed notice of change of name to the Wrightsman Petroleum Co. The company is organized under Delaware laws.

THE UNION SOAP CO., 214 North Pearl St., Baltimore, Md., has filed notice of reduction in capital from $50,000 to $12,000.

Frederick J. Telovitz has been appointed receiver for the GOODWEAR LEATHER MFG. CO., INC., Raritan, N. J.

THE ALBIAN OIL CO., Tulsa, Okla., has filed notice of increase in capital from $12,000 to $250,000.

THE DERBY DOME-WYOMING OIL CO., St. Louis, Mo., has filed notice of increase in capital from $50,000 to $1,500,000.

THE GUANTANAMO SUGAR CO., 129 Front St., New York, N. Y., has arranged for a new preferred stock issue to total $1,500,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its twenty-fourth annual meeting at St. Louis, Feb. 27 to March 3, 1922.

AMERICAN CHEMICAL SOCIETY will hold its spring meeting at Birmingham, Ala., April 4 to 7, 1922.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting in Baltimore, April 27, 28 and 29, 1922.

AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its next convention and exhibit at Rochester, N. Y., during the week of June 5, 1922. Meetings will be held in the spring instead of in the fall as heretofore

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its spring meeting in New York the week of Feb. 20, 1922.

AMERICAN SOCIETY FOR STEEL TREATING, sectional meeting, Friday, March 3, Engineering Societies' Building, New York City.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its twenty-fifth annual meeting June 26 to July 1, at Atlantic City, N. J. Headquarters will be at the Chalfonte-Haddon Hall Hotel.

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY will hold a meeting at Lyons, France, June 27 to 30.

IRON AND STEEL INSTITUTE (British) will hold its annual meeting on May 4 and 5 at the House of the Institution of Civil Engineers, Great George St., S. W., 1, London.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

NORTHWEST MINING ASSOCIATION will hold a convention in the Chamber of Commerce Bldg., Spokane, Wash., Feb. 14 to 18.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following meetings are scheduled to be held in Rumford Hall, the Chemists' Club, New York: Feb. 10—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting; March 10—American Chemical Society, Nichols Medal; March 24—Society of Chemical Industry, regular meeting; April 21—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting; May 5—American Chemical Society, regular meeting; May 12—Société de Chimie Industrielle (in charge), American Chemical Society, Society of Chemical Industry, American Electrochemical Society, joint meeting; May 19—Society of Chemical Industry, regular meeting; June 9—American Chemical Society, regular meeting.

Bootlegging in Chemical Apparatus

THERE are a few fly-by-night concerns that claim to be "just starting out in business" that have, of late, been diligent visitors at laboratories of schools and colleges to offer chemical apparatus. They rarely have catalogs of their own, but refer to those of established dealers under specific numbers to indicate their wares. Their prices are low; enough below current quotations to get a hearing.

Now we sympathize with institutions of learning in their desire to get scientific apparatus as cheaply as they can, although we are not in favor of duty-free materials for them. We have the glass and porcelain industries well established in this country and we want to keep them. It has been suggested that universities, colleges and schools should get their laboratory equipment at approximately cost prices, but we are told that the educational demand represents about 80 per cent of the total. To sell 80 per cent of their goods at cost and then to make their living out of the remaining 20 per cent would be asking too much from the manufacturers and dealers. They are not fashionable physicians.

The Just Starters in the business of selling chemical apparatus, to whom we refer, are likely to be sympathetically received because of their low prices. Then when they make a sale, being so young and all, and having such a "slight margin of profit," they often ask for a considerable cash payment in advance. When the shipment comes in it turns out to be job lots of German and Japanese goods that are below the standards of quality maintained by reputable concerns. In the meantime the Just Starters lose interest as soon as they have disposed of their bargains and then are difficult to find. We are told that one large state university was seriously embarrassed by this very kind of a trick.

The late CHARLES BASKERVILLE, most of whose students were far from affluent, and who had to purchase with great care to keep within his appropriations, insisted on American-made goods and would deal only with established concerns. His point was that the need of these industries in America was greater and of more importance than his own personal convenience.

But whatever apparatus be purchased, whether American-made or imported, the only safe rule for colleges and universities is to buy from well-established and responsible houses. Just now when most things are at sixes and sevens and the prices of all sorts of merchandise seem to have no top and no bottom, the irregular dealer is abroad in the land. The wise buyer deals with a seller who has both experience and character and a responsible house behind him. Job lots of laboratory wares from unknown sources may cost less to buy, but they are likely to drag a trail of increased expense behind them, not only in work but occasionally a human eye into the bargain.

Ford's Offer Up to Congress

NEARLY seven months has elapsed since Mr. FORD made his first offer to purchase the power and nitrate plants at Muscle Shoals. This was formally presented to Secretary WEEKS on July 8, 1921, and was the basis of subsequent negotiations that resulted in a modified offer signed by Mr. FORD on January 25, 1922. The latter has now been transmitted to Congress by the Secretary of War with his recommendations and a careful business analysis of the entire proposal. The matter is now up to Congress.

Mr. WEEKS' analysis of the Ford proposal presents such a clear picture of the subject that we have reproduced it in whole in this issue, believing that our readers will be interested in getting more detail than was published in the daily press. For the final disposition of Muscle Shoals will have a tremendous bearing on the future of the fertilizer industry in this country, as well as on the whole industrial development of the South. In our last issue we pointed out some of the things that Mr. FORD is likely to do if he gets the plants.

A careful reading of Mr. WEEKS' analysis will impress the reader with the fact that Mr. FORD'S primary interest in Muscle Shoals is cheap power, and that he asks to have the nitrate plants thrown in at a knock-down price. His whole approach to the subject is based on his desire to obtain cheap power for his industrial projects, and on his estimate of what he can afford to pay for it. If the reader will keep this in mind, he will understand why Mr. FORD goes into considerable detail in his proposal to buy the dams and power plants, and then casually imposes as one of the conditions of his offer that the United States sell to him Nitrate Plants Nos. 1 and 2, the Waco lime quarry and the Gorgas-Warrior steam plant, with all appurtenances, for $5,000,000. These plants cost the government $85,000,000, and have a scrap or salvage value estimated at from $9,000,000 to $16,000,000.

Mr. FORD'S modified offer is more advantageous to the government than was his original proposal. His suggested rentals for the dams and power plants are more nearly adequate. Likewise his proffered compensation for maintenance is increased, and his plan for amortization has been improved. The clause relating to renewal of leases at the end of 100 years is more favorable to the government. All of these points are discussed in detail by Secretary WEEKS.

But there are points yet to be modified if, in the opinion of the Secretary of War, the proposal is to meet the approval of Congress. The present offer apparently is deficient in assurance that the contracts once entered upon by Mr. FORD will be carried out, or that some penalty will be imposed for failure to perform. The cost of acquiring certain lands and flowage rights in connection with Dam No. 3 should be included in the

sum upon which Mr. FORD is to pay interest at the rate of 4 per cent. Instead of paying the United States a fixed sum for maintenance of dams and locks, Mr. WEEKS suggests that Mr. FORD assume the cost and responsibility for maintenance just as the latter proposes in the case of the power plants. Finally, Congress shou'd see to it that the regular federal regulations are applied to the sale of power to custom buyers, and that the lease period be 50 and not 100 years. So much for the power project.

As for the nitrate plants, Mr. FORD binds himself to operate Plant No. 2 at its approximate present annual capacity for the production of nitrogen and other fertilizers, and to maintain the plant in readiness for the manufacture of explosives and to turn it over to the United States for that purpose when needed for the national defense. But for the rest of the outfit—Nitrate Plant No. 1, Waco quarry and Gorgas-Warrior steam plant—he is under no obligation to maintain or operate them, nor is there legal obstacle to his disposing of them Should he pursue the latter course and obtain their estimated salvage value, he would have left the $67,000,000 Nitrate Plant No. 2 for about $400,000.

Congress may well ponder the propriety and wisdom of throwing away these properties for a song. True, nitrogen preparedness is worth much, but perhaps not that much. Mr. FORD is still the only bidder. We must remember that the Air Nitrates Corporation that built the plant has, under the terms of its construction contract, an option to buy Nitrate Plant No. 2 on as favorable terms as those offered by a successful bidder, and the Alabama Power Co. has the same option in relation to the Gorgas-Warrior steam plant. Nobody knows what these companies think the properties are worth, but if Mr. FORD is a successful bidder their actions will be a measure of their valuation of the plants. The inevitable delay that will ensue in Congress in consideration of Mr. FORD'S offer may not be an unmixed evil, for it may bring other bidders into the market. Furthermore if Congress acts on Mr. WEEKS' recommendations, particularly in regard to the shortened lease period which we have consistently advocated, Mr. FORD may withdraw his proposal and the whole matter can be deferred to a more propitious time.

With Hoover At the Helm

BUSINESS is gradually coming to realize that it has friend at court in the person of the Secretary of Commerce. He has come to be regarded as the business man of the present Administration, for he stands out as one among the few who can share the viewpoint of industry and understand its problems.

If for no reason other than the record of his accomplishments in the Department of Commerce, Mr HOOVER is deserving of the confidence and gratitude of American business men. Under the past 8 months of his direction this branch of the government has been developed into an effective agency of industrial service. The three Bureaus of Foreign and Domestic Commerce, Standards and the Census have become points of active and intimate contact with trade and commerce. The records show that 127 trade associations are now working in close co-operation with the department. The Bureau of Foreign and Domestic Commerce alone has forty co-operating committees representing 60,000 men who are interested in the promotion of our foreign trade. In all, ninety committees form contact with the department, and through these committees 350,000 engineers, merchants and manufacturers are constantly receiving market information of actual dollars-and-cents value.

American firms concerned with the development of our export trade have learned to profit by the government's studies of foreign markets, as well as the definite inquiries and business advice published each week in the new *Commerce Reports*. Furthermore, the work of expert industrial representatives in many foreign countries and their official assistance in negotiations with foreign governments have been of genuine service in selling American goods. Nor has the domestic trade been neglected, although in the past the charge was often made that foreign trade had always received the predominant share of the bureau's attention. The program for elimination of waste and the work which has been done along the lines of standardization and simplification have been outstanding features in our national reconstruction. *The Survey of Current Business*, with its useful statistics on production, consumption, prices and trade, has proved a reliable guide to industry. Last but in no way the least of the new activities has been the work of the special commodity divisions. With more than a dozen industries actually represented in the bureau's organization it has been possible to interpret and make effective a great mass of information.

The questions naturally arise, What is left to be done? What are Mr. HOOVER'S future plans for the department? Briefly they are these: (1) To improve personnel conditions, for if these bureaus are to serve business effectively they must be competently manned; and (2) to broaden and enlarge the activities of the department until it can adequately represent industry in the government. That that hard-headed business man, the Director of the Federal Budget, was convinced of the soundness of these plans is evidenced by the proposed budget, which provides for an increase of about $750,000 in the department's appropriations. Much of this is to be spent for increasing the meager salaries now paid to technical and scientific employees.

If the appropriation is passed by Congress, approximately $270,000 will be used to increase the number and service of the expert commodity divisions. It will be remembered that in Mr. HOOVER'S original plans one of the commodity divisions was to represent the chemical industry. That this part of his plans should miscarry was not the fault of the department but rather because the industry or the trade association representing it at that time failed to accept the government's offer of co-operation. Fortunately, however, the chemical industry is beginning to recognize its mistake, and there is reason to believe that if the increased appropriation is obtained a chemical division will be of the first to be organized.

In the meantime Congress must be convinced that industry really wants this work continued. If Mr. HOOVER'S plans are to materialize, the budget must be approved and the increased appropriations granted. The chemical industry can and should do its share. Its trade associatons, firms and individuals can make known their desires at the hearings of the congressional committees which are now in session. If we are in earnest, if we are willing to back up the work of the Commerce Department, let's say so—and in no small voice.

The Passing Of a Friend

ON ANOTHER PAGE we print a biographical sketch of the late CHARLES BASKERVILLE. In addition to being a persistent investigator and voluminous author he was also a great teacher. "If you can't make your students believe in you and trust you, how can you teach?" he often asked. He was always accessible to his students; there was none too humble to find a ready response in him so far as his multifarious duties gave him the opportunity. Outside the college he was more reserved and held rather closely to his friends. He was the best of companions, a delightful raconteur, a very prince of good fellows—but he hated vulgarity. He was unashamed of his convictions; and his convictions were always honorable. They never wavered toward his advantage. A proud man withal; but "pride is no sin except when one will not live up to it." He lived up to his pride. He believed in the bigness and in the dignity of his profession. This very attitude sometimes caused others to misjudge him. He was an aristocrat in breeding and in sentiment. And yet whoever of good will would give himself the pains to get closer to him invariably found him at once both fair in mind and genial in disposition.

He had indeed a genius for friendship. It was singularly pleasant to tell him good news and it was helpful to go to him in the days of trouble. That is why, to those who were near to him, his passing takes some of the tang out of life and the mellowness from oncoming age. But *sursum corda!* Who would not rejoice and be glad in the benediction of such friendship?

Alcohol From Water Gas

IN A RECENT issue of *Chemical Age*, London, C. G. CALVERT states that in his small-scale model plants at work in England he is making ethyl alcohol from water-gas mixtures at the rate of one gallon of ethyl alcohol per 1,000 cu.ft. of gas, and that there is every indication that the efficiency will be greatly increased in large-scale plants. He says the process is extremely simple, and that it works constantly under all conditions likely to be met in practice.

Lately we printed the cost of water gas as presented at a hearing before the Board of Public Utility Commissioners of New Jersey by the general manager of the Public Service Corporation. He placed it between 53 and 57 cents per 1,000 cu.ft. for all parts of the state, with an estimate of 11 per cent for gas unaccounted for. But in making gas at the source for alcohol production, without enrichment or loss in pipes, the figure should be much lower. With this cost brought down and the efficiency, as predicted by Mr. CALVERT, brought up, the process begins to look interesting.

That is, it looks interesting anywhere except in the United States. Here the persistent incapacity of our law-making and law-enforcing authorities to distinguish between alcohol in industry and alcohol in drink makes the production of this great solvent, antiseptic and needed chemical almost impossible, irrespective of the fact that without it many industries must close down.

It may be that in time the virulence of the present drive against the industrial alcohol industry by the Anti-Saloon League and its supporters will give way to enlightenment, but as yet it is exceedingly difficult to get a hearing before ears that will hear. As an example of the prevailing means used in debate there was lately put to a number of physicians the question whether they held it to be necessary to administer ethyl alcohol in any form. One cheerful and successful practitioner declared that he never prescribed alcohol for internal use. Where whiskey or brandy was prescribed by other physicians he obtained just as good results with aromatic spirits of ammonia. This has been largely quoted. But the fact that while whiskey contains about 45 per cent of alcohol, aromatic spirits of ammonia contains 63 per cent of it, has been suppressed. That is the kind of "oral argument" that is popular. Wide-mouthed argument, we call it.

The Long Reach Of Romance

THIS is a story of Buffalo Bill. We do not vouch for the correctness of the details; we give it as we heard it and as such it will answer our purpose. While he was an army scout he was attached to a battalion under General CROOK. The Sioux were troublesome, and once when the battalion in question was encamped in the Bad Lands it was surprised by YELLOW HAND with his braves. They came in the night and established themselves on high ground, where they had considerable advantage. YELLOW HAND was a true savage; he neither gave nor asked for quarter; he was a fighting man. He sent a boastful challenge to the officer in command. "Let any one of your men," said he, "come out in the open and fight me singlehanded, and I will call it a battle!" The Colonel was about to scorn the message, when CODY said, "Colonel, I know their ways. If we don't agree to this we shall be sure to lose a considerable number of men, even if we defeat them, for they are stronger and have the advantage of position. But if we accept the challenge they will abide by the result and leave when the fight is over. Let me accept!"

Never mind the argument; in the end Buffalo Bill accepted. The two men were to face each other a quarter of a mile apart, before the assembled hordes, each on horseback and armed with a rifle and a knife. It was to be a duel to the death. No rules and no quarter.

It began and both fired. YELLOW HAND missed and Buffalo Bill hit his opponent's horse, which stumbled and fell. In the fall YELLOW HAND'S rifle slipped out of his grasp. Quickly he drew his knife and stood, awaiting his antagonist. *Buffalo Bill alighted from his horse and threw away his rifle.* Then he too drew his knife and approached YELLOW HAND on foot, to meet him on even terms. The fight proceeded to a finish; to the death of YELLOW HAND. Then the braves retreated and the battalion marched on.

That is an epic of the West, isn't it? It has the real, thirteenth century tang to it. Think of what CARL SANDBURG could do with the story!

Well, where is an epic of chemistry? We can't find one in chemical warfare. That is modern and wholesale and impersonal. It involves suffering and agony and death, but we can see only the victims; we miss the hero. What is wanted is the romance. The romance is there, but who has the wit to find it?

Before us is the whole field of literature to be spoken or read or acted. The moving picture people are straining every nerve for scenarios. Far too many chemists are now in idleness. Some of them have imagination. Some can write. And in the romance of science is the chance. It would instruct the public and be a good thing for science if they were to get busy.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, Italy, Jan. 6, 1922.

DECEMBER was a month of little accomplishment for the Italian chemical industries, although the workpeople had returned to their work and were willing to produce. This was due to the great fluctuations in the value of the Italian lira, which caused many to believe for a time that a strong recovery had begun. This idea was soon dissipated, however, by a further fall. In December the Leghorn chemical workmen, who had not reached an agreement in November, accepted the conditions proposed by their employers and returned to work. Many foresee that their example will be followed in other parts of Italy.

FERTILIZERS

The fertilizer market was weak, owing to the persistence of the dry weather, which discouraged many farmers in their cultivation operations, so that they would not draw the superphosphates from the works in many quarters. Despite this, the outlook for the present year is promising and a number of opportunities have been created through the special conditions prevailing. Thus the stocks of sulphate of ammonia fell to a very low point, Germany having prohibited all exportation and England having the absolute monopoly of the market. In the case of nitrate of ammonia, which gave very promising results when tested for fertilizing purposes, the demand was light in December, but will probably increase later. For these reasons offers of such products should be well received. In the case of Chilean nitrate of soda, especially low offers were made for immediate delivery, whereas for delivery during the next months an increase of 20 lire per ton and per month was asked. The imports of mineral phosphates reached 19,585 tons during September, 1921, against 39,530 tons during the same month of 1920, and during October 42,537 tons, against 23,865 tons during the same month of 1920.

GLUCOSE

In view of the progress made in the manufacture of glucose, the production of which reached 8,400 tons in 1918, the Italian Government arranged toward the end of the year a manufacturing tax of 1,200 lire per ton in the case of the crystalline or solid product, and of 600 lire per ton in the case of the liquid product. Besides this tax a yearly working license, ranging from 50 to 121 lire, is also necessary. The imports of solid glucose reached 42 tons during the first 6 months of this year, against nothing during preceding years, whereas the imports of liquid glucose were of 727 tons, against 3,660 tons in 1920 and 705 tons in 1919 during the corresponding period. Of the second importations of this year, 681 tons came from the United States of America, 29 tons from Holland and the remainder from other countries. The total exports reached only 5 tons.

SUGAR

The continual change in the policies of the Italian Government in regard to regulating the importation of sugar and the lack of shipping facilities from Cuba have rendered impossible a large importation of sugar from this source and the importers could satisfy the needs of the industries using this product only by passing comparatively small orders to the United States, England, Belgium, South America, Holland, Java and other countries. Such a state of affairs caused the German Government to propose the refining of 1,000,000 tons of sugar to be purchased in Cuba for Italy and France, on account of war reparation. However, Italy was not willing to accept the arrangement.

A new law increased the taxes on the importation of sugar, with the idea of protecting the national industry against the effect of the continental reductions in the foreign offers, while other laws limit the importations for each plant to 6 months' requirements and provide for permits for deliveries to be made simultaneously to several firms in the same town.

PEPPERMINT OIL

Owing to the excessively dry weather, the essential oil yield of the Piedmontese peppermint plant was above normal, and the production for the year would have been correspondingly large if the growers had not insisted on a price so high that it could be accepted only by those distillers that had previous contracts. The essential oil of the new mint harvest contains 50 per cent of menthol and is stronger than the product of the last year. The yield of mint oil was calculated to reach 300 g. per 100 kg. of herb treated. The plant, through the excessive dryness, remained low during the first period of its growth, and many ascribe to this fact its superior concentration in essential oil. In the first half of 1921 the imports of peppermint oil reached 4,518 kilos, against 9,462 kilos in 1920 and 3,226 kilos in 1919 for the same period. The exports reached only 796 kilos, against 2,894 kilos in 1920 and 7,742 kilos in 1919.

SULPHUR INDUSTRY

To bring to a speedy conclusion the negotiations that have been pending for some time regarding the troubles of the Sicilian sulphur miners special concessions were arranged for the miners, with the hope that they will contribute toward increasing the yield of the mines, permitting a reduction in the cost of extraction. In the meanwhile the prices of all sulphur products have fallen considerably, owing to American competition and the reduced demand on the home and foreign market, caused by the unfavorable season.

HYDRO-ELECTRIC PLANTS SHUT DOWN BECAUSE OF LOW WATER

In order to permit the slow refilling of the mountain reservoirs whose supplies had been depleted by the extreme dryness of the past months, the Italian Government stopped the supply of all electric current to the industries from midnight of Dec. 24 to midnight of Jan. 1 in all the provinces of Lombardy and in the provinces of Reggio, Modena, Parma and Piacenza. In the provinces of Genoa, Bologna, Novara and Alessandria this suspension was only partial. On their part the state railways reduced the number of trains hauled by electric engines and in some cases increased the use of steam locomotives. In the meanwhile studies are being made for the purpose of interconnecting the different Italian lakes, thus making part of their water available for producing electric power. Some Italian industrials insisted on special facilities being arranged for encouraging the importation of machinery for the working of heavy combustible oils. No great development is, however, foreseen in this direction, as motive power thus produced costs more than that obtained through coal, which in turn is six times as dear as that produced through water power.

The German and American Synthetic-Ammonia Plants*—I

Construction and Operation of U. S. Government Plant at Sheffield, Ala., Compared With That at Oppau, Germany—Water and Fuel Requirements Are Given and General Facilities Such as Housing of Equipment and Process Are Described

By R. S. TOUR

GREAT interest has arisen within the last few years in the chemical industry, looking toward the commercial development of synthetic-ammonia plants. Outside the chemical industry the agricultural interests are vitally concerned in the successful development of nitrogen-fixation processes. And in addition, it is of great importance to the United States Government, from a military standpoint, that there be a thriving nitrogen-fixation industry in this country. Although the War Department of the United States built, and attempted to operate as a war emergency, the first synthetic-ammonia plant of commercial size outside of Germany, still it feels that during normal times the development of such processes should be carried on by private interests. The experience and information that has been gained by the War Department will be of value under these conditions in so far as it is made available to the industry. As a step in this direction, the War Department has, therefore, acceded to the request of the American Institute of Chemical Engineers that a paper be submitted describing the German and United States synthetic-ammonia plants.

The direct synthetic-ammonia process has been described in a previous paper[1] by the author, which shows the steps and incidental processes involved in the industrial manufacture of ammonia by direct synthesis from its elements. The purpose of the present paper will be to indicate the methods of operation and types of apparatus and equipment that have been developed in the German and in the American plants. The plants in Germany and the United States are as yet the only industrial synthetic-ammonia plants producing the hydrogen and nitrogen gases by the water-gas and producer-gas methods. Some other smaller plants have been developed on the Continent for synthesizing ammonia from hydrogen produced electrolytically, but such processes are not generally applicable and have not been considered here.

German Plants

Two plants were built in Germany, one at Oppau with an annual capacity of 100,000 metric tons of ammonia and one at Merseburg with 200,000 tons rated capacity (respectively 110,000 and 220,000 short tons). Preliminary work on the Oppau plant was started in 1912, and by 1914 a pilot plant of about 10,000 tons annual capacity was in operation. The main plant construction was started in 1914 and the rated capacity of the entire plant was reached in 1917. The Merseburg plant was built mainly during the war and three-fourths of its rated capacity was in operation before the armistice was signed. The Merseburg plant has since been completed and can now develop its entire rated capacity. Both plants were designed and built by the Badische Anilin und Soda Fabrik after several years of experimental and development work. The same company also operated the plants, although the German Government furnished aid to the company in many ways during the war.

American Plants

One synthetic-ammonia plant was built at Sheffield, Ala., by the United States Government as a war emergency measure in 1917. This plant had a rated annual capacity of 10,000 short tons of ammonia. In the main it followed the principles and processes tried in Germany, but construction was based directly upon experimentation and designs developed by the General Chemical Co. over a preceding period of several years' duration.

After negotiation between the United States Government and General Chemical Co., arrangements were made for the construction and operation of the plant at governmental expense, but according to the company's plans and under its supervision. Experimental operation was started in June, 1918, but continuous operation was not realized up to the time the plant was closed in January, 1919. Another synthetic-ammonia plant is now being built at Syracuse, N. Y., by the Atmospheric Nitrogen Corporation, a company formed by the Solvay Process Co. and the General Chemical Co. It is expected that this plant will start operations within the year. Several other corporations have been formed in this country within the last few years for the purpose of investigating or developing nitrogen fixation, but as yet none has proceeded with its plans far enough to start construction.

After the Sheffield plant was closed, the Nitrate Division of the Ordnance Department very much desired that the development of the process be continued, but no satisfactory arrangements could be concluded with the General Chemical Co. for the latter to continue experimentation and plant development at Sheffield. The government then felt that it must proceed independently and the United States Fixed Nitrogen Commission was sent to Europe in June, 1919, to investigate the status of nitrogen-fixation there, particularly the Haber plants of Germany. During the summer of 1920, plans and redesigns of the Sheffield plant were undertaken, looking toward the substantial modification of the plant, to be followed by another operating period for further development. The general plans and programs are now nearly complete, but are being held in abeyance, awaiting commercial development of the process by private industry. In the meanwhile, the government

*Contribution from the Nitrate Division, Ordnance Department, U. S. Army. Published by permission of the Chief of Ordnance and presented at the thirteenth semi-annual meeting of the American Institute of Chemical Engineers, held at Detroit, Mich., June 20-25, 1921.

[1]R. S. Tour, *J. Ind. Eng. Chem.*, vol. 12, page 844 (1920).

desires to aid the industry in any way possible, by making available some of its general information concerning the art.

Products of German and American Plants

The Oppau plant in Germany is the one to be described in this paper, since the writer, as a member of the United States Fixed Nitrogen Commission, during the summer of 1919 was fortunate enough to spend a week at that plant and inspect it thoroughly, submitting a report, dated Nov. 1, 1919, covering this inspection. This report has served as the basis for much of the material and all the sketches relating to the German plant. Previous to the visit to the Oppau plant, the writer had been in direct touch with all the development and initial operation of United States Nitrate Plant No. 1 at Sheffield, Ala., and the descriptions and statements given here concerning that plant are from his report on the work there.

The point of view taken in this comparison of the Oppau and Sheffield plants will naturally be somewhat different for each of the two plants, in view of the fact that the former was in its final stages of development and was an operating success at the time of inspection, whereas the Sheffield plant was never out of its initial development period.

Only the synthetic-ammonia portions of the respective plants will be considered here, although the German plant included several processes for the utilization of the ammonia, such as (1) the oxidation of part of the ammonia to nitric acid with the final production of ammonium nitrate; (2) the interaction of ammonia and carbon dioxide gas with gypsum to give ammonium sulphate; (3) the reaction of the ammonia-soda process between ammonia and carbon dioxide gas with brine to give ammonium chloride and soda. Auxiliary processes involving the use of carbon dioxide are very attractive in view of the fact that the gas is a byproduct in large quantity from the process. At the Sheffield plant there were installed ammonia oxidation, absorption, concentration, neutralization and crystallization plants for the manufacture of the necessary war product, ammonium nitrate.

The Process

Before taking up the description of the plants, it might be well to mention the steps involved in the synthetic-ammonia process.[2]

Manufacture of Hydrogen and Nitrogen—Hydrogen is obtained by the "water-gas oxidation" method, wherein water-gas produced in standard machines is caused to react further with an admixture of steam in the presence of a catalyst according to the reaction $CO + H_2O \leftrightarrows CO_2 + H_2$, converting (oxidizing) most of the carbon monoxide to dioxide and generating additional hydrogen in so doing. The nitrogen in the mixture may be obtained by supplying air into the gas generator during the manufacture of the water-gas, or by the injection of air into the oxidation stage of the process, or by the admixture of straight producer-gas to the water-gas before oxidation.

Purification of the Gases—The purification of the gas mixture is accomplished by high-pressure water-scrubbing to remove carbon dioxide, followed by ammoniacal cuprous solution scrubbing to remove carbon monoxide and incidental impurities. Auxiliary or special purification may further involve scrubbing with hot or cold caustic solutions, drying with soda lime or similar treatment.

Manufacture of the Ammonia—The synthesis of the ammonia is finally accomplished in one portion of a continuous circulating system by passing the nitrogen-hydrogen mixture at high pressure and high temperature over a suitable catalyst. The ammonia synthesized

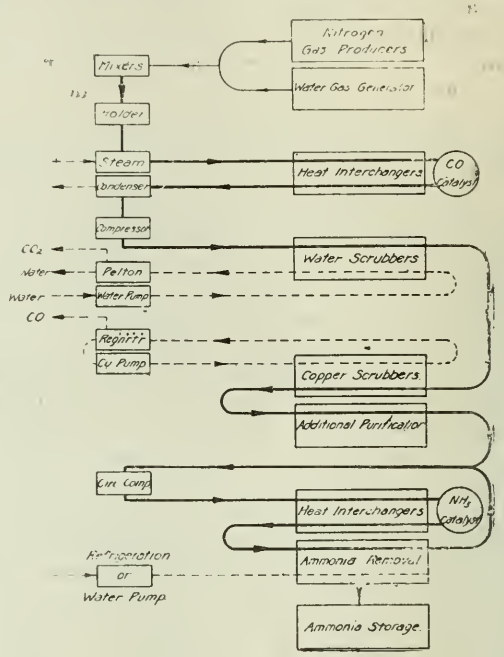

FIG. 1—DIAGRAMMATIC FLOW IN THE DIRECT SYNTHETIC-AMMONIA PROCESS

is removed continuously by liquefaction or absorption in another portion of the circulating system, while the uncombined gases repeat the cycle together with additional gas mixture introduced to replace that synthesized.

General Facilities of the Oppau Plant

The German plant is situated at Oppau, on the Rhine, about two miles below Ludwigshafen and about a mile from the main chemical plant of the Badische Anilin und Soda Fabrik, which controlled the plant and process.[3] The Oppau plant covers 175 acres of ground and much more is available if necessary. There are about 250 buildings or structures of various sizes and shapes. All the main buildings are substantially built of brick and steel and are logically arranged with carefully laid out streets. Necessary trackage, transportation facilities, cranes, etc., are provided throughout.

Primary central power for the plant is furnished by a producer-gas-engine installation of 10,000-kw. capacity and a steam turbine station of 18,000 kw. capacity. Electric power is generated and distributed at 5,000 volts, three phase, fifty cycles. In addition there are steam and gas engines for local power production at various points throughout the plant. Comparatively little of the central station power is consumed for the synthetic-ammonia manufacture, since, where compressors or pumps of large capacity operate continuously, they are directly driven by gas or steam engines.

High-pressure steam (175 lb.) is furnished by water-tube boilers equipped with superheaters, mechanical

[2]Editor's Note: Further consideration of these steps is given in succeeding installments of this article.

[3]Reference should be made to the articles on the "Manufacture of Synthetic Ammonia at Oppau, Germany," published in Chem. & Met. Eng., vol. 24, pp. 305-8, 347-50 and 391-4 (1921).

grates and forced draft. The total heating surface is about 60,000 sq.ft., divided among thirty-two boilers of several sizes. The fuel is normally lignite, although some of the boilers are equipped for burning tar and oil and others for producer-gas. Low-pressure steam (50 to 60 lb.), necessary in different parts of the process, is supplied by tubular boilers heated by gas-engine exhaust.

The main fuel for the plant is lignite in the form of briquets available near by in the valley of the Rhine. These are used for steam generation and for the producer or power gas manufacture. Considerable hard coal, or anthracite, is also used. The coke needed was purchased during the war, awaiting the completion of the byproduct coke-oven installation on the grounds. The total fuel consumption of the plant at capacity, including ammonia utilization processes, is about 2,500 short tons per day, most of which is delivered from barges on the Rhine and taken care of by elaborate coal-handling equipment.

Water is supplied by a pumping plant on the Rhine, operated with electric power and also by gas engines. All the water is filtered through sand and finally supplied to the plant at a pressure of 60 to 70 lb. The total water plant capacity is about 100,000 gal. per minute.

Shops and Laboratory at Oppau

The plant has large machine, pipe and repair shops. The equipment of these shops is complete in every respect and large enough to take care of the largest piece of apparatus in use at the plant. The administration offices and main research laboratory are housed in a beautiful building, fully and completely equipped, costing in all about 3,000,000 marks. This building is in addition to the different routine testing laboratories and superintendents' offices located in the individual buildings where operating control is necessary.

Each step of the process is housed in a separate building and in many cases the high-pressure apparatus is adjacent to, but outside of, the building assigned to it. The building itself contains the pumps, engines and other auxiliary apparatus together with the control valves and lines, which are carried through the walls from the apparatus outside and thus afford safety and shelter to the operators. Each step of the process involves several identical items of apparatus, operating in parallel; thus allowing the failure or repair of any single item without jeopardizing the balance of the process. The number of items installed is different for the respective steps of the process. No series of apparatus for all the steps is connected to form complete independent units for the entire process, but the entire plant works as one single unit with a productive capacity of 300 tons of ammonia per day.

General Facilities of the Sheffield Plant

The American plant is situated on the outskirts of Sheffield, Ala., about a mile from the Tennessee River. The plant proper occupies about 100 acres, although the plant has title to much more surrounding property. There are perhaps forty buildings, some of which are of a temporary nature, although the main process buildings are of substantial and modern construction.

Primary power for the entire plant is furnished by turbo-generators totaling 5,000 kw., generating at 2,200 volts, three phase and sixty cycles. There is no power generation about the plant other than the above. The power that is used for the synthetic-ammonia process is transmitted through rotary converters and used at 250 volts d.c. The main purpose of the d.c. power was to allow a more flexible speed control in the operation of the synthetic process plant.

High-pressure steam (190 lb.) is obtained from eight Stirling boilers of 500 b.hp. each, equipped with superheaters, stokers and forced draft. There is no installation for low-pressure steam, but this is obtained through a reducing valve from the high-pressure main or is "bled" from the turbines. The fuel is bituminous coal except in the gas generators, where coke is necessary. The coal and coke are brought into the plant grounds by rail and are normally obtained from nearby localities.

The use of direct-current power at Sheffield, Ala., is a definite inefficiency which is chargeable to the development of the process at that plant. In view of the fact that low-pressure or exhaust steam is necessary, it would have been much more advantageous to operate the experimental equipment in place with reciprocating steam engines properly equipped with throttle or cut-off adjustments, these engines exhausting into the exhaust manifold for supplying the steam requirements of the plant. High-pressure steam used for low-pressure purposes is expensive and the bleeding of steam turbines puts them at a disadvantage in comparison with reciprocating engines.

Water is supplied by a pumping station situated about two miles distant near a large spring and creek having the necessary capacity all year round. There is a filter plant on the plant grounds where all the water used may be filtered through sand and finally supplied to the plant at a pressure of 40 to 50 lb.

Shops and Laboratory at Sheffield

The plant has but one small machine shop and general repair shop and the equipment there installed is not sufficiently large to take care of the larger pieces of apparatus connected with the synthetic-ammonia process. If such work should become necessary, the apparatus would have to be shipped to a properly equipped machine shop in some other locality. The administration and control laboratory buildings are of temporary nature and have been held over from the construction period. The plan was to erect permanent buildings in accordance with their necessity at some later date.

The lack of large enough and properly equipped machine and repair shops was found to be a serious handicap immediately after starting operation. The omission of a crane for moving the heavy apparatus in the main ammonia process building was another serious oversight. The lack of an administration building was not seriously felt, but the need of a properly equipped research laboratory with the necessary personnel immediately became evident. The latter is a very necessary adjunct to the process in such a stage of development as it was at Sheffield.

Practically all the steps of the process are housed in one large building. All the high-pressure apparatus, together with pumps, motors and controls, are also within the building. Only the water-gas machines and their auxiliaries are separately housed. It is evident that this general scheme is undesirable in a commercial plant, especially one in a developing stage, since the rupture or explosion of one piece of apparatus endangers the entire equipment of the process. The crowding neces-

sary to place so much equipment under one roof caused many inefficiencies in proper development or operation.

The gas purification and ammonia-synthesis portion of the plant consists of three separate and independent units not interconnected although in the same building. The different steps of the process in each unit involve but single items of apparatus with spares where considered necessary. The operation of independent units with but single items of apparatus in some of the steps requires the shut-down of the complete unit in case of a failure to function of any single item. In view of all these handicaps it speaks well for all concerned that operation resulted in no serious mishaps and that success seemed finally within grasp.

Unit No. 1, the only unit upon which complete operation was attempted, and Unit No. 2 were rated at 15,000 lb. of anhydrous ammonia each per day. Unit No. 3, which was never completely installed, carried larger apparatus than the other units and was rated at 30,000 lb. of ammonia per day.

This article is to be continued. Part II will describe the manufacture of hydrogen and nitrogen, Part III the purification of these gases, Part IV will discuss the manufacture of ammonia and Part V will present some consideration of costs.

Permanence of Steel Gages

AT A recent meeting of interested manufacturers, called by the Ordnance Department, U. S. Army, for the purpose of considering ways and means for more satisfactory gages, it was pointed out that the most difficult problem to be solved is that of finding a steel that will "stay put"—i.e., one in which the dimensional changes after hardening are negligibly small. It is well known that at present the dimensional changes occurring in hardened steels during "aging" are very irregular in magnitude, direction and rate of change. Claims reported to have been made for a certain steel which is absolutely uniform in behavior on hardening were discounted.

No single composition or heat-treatment should be expected to be satisfactory for all types of gages; ease of machining, hardness of surface, resistance to abrasion, resistance to corrosion, freedom from distortion on hardening, and other characteristics being of different relative importance under different conditions of manufacture and use. Brinell hardness or file hardness is not necessarily a measure of abrasive resistance, and it is well known that alloy steel gages will outwear carbonized plain steel gages of much greater apparent hardness.

For plugs and rings a tool steel of 1.15 to 1.20 per cent carbon had been found satisfactory. For this purpose a steel with good wearing qualities and free from hard or soft spots is of prime importance. Freedom from slight dimensional changes after hardening is not so important for this class of work. From the information now available it would seem that ball race steel is best suited to the purpose. Manufacturers of ball race steel have specifications as to quality, but these may be found inadequate.

Dr. Mathews stated that in a series of experiments conducted by him in 1920 it was found that by differing the heat-treatment the dimensional changes could be very largely controlled. Extreme hardness and high resistance to abrasion are not compatible with freedom from dimensional changes after hardening, and it may be necessary to sacrifice hardness to some extent in order to secure stability of dimensions.

Heat-treatments that are supposedly the same often differ widely, and the heat-treatment as actually carried out in the plant may differ markedly from the instructions given and the program laid out. It may, therefore, be possible that observed differences in behavior of steels are due to differences in heat-treatment even when the treatment is supposedly uniform. Many factors affect the heat-treatment, rate of heating and time at the maximum temperature being perhaps the most important. The presence of chromium has a decided effect on the softening under heat; chromium steel softening at a lower temperature than straight carbon steel. It had been found to be good practice to draw at as high a temperature as possible without reducing the hardness too much. The beneficial effect of chromium in reducing corrosion and discoloration of polished surfares was also mentioned.

In work on gage blocks it was found that the steel giving the smallest dimensional change on hardening did not always show the smallest subsequent change; nor did the rate of change after hardening always decrease with time. Certain blocks showed very irregular changes of length, some remaining practically constant for one or two months or more, and then suddenly undergoing very considerable changes.

Standard Code of Lighting for Mills

The code of lighting for factory mills and other work places, based upon earlier codes issued by the Illuminating Engineering Society and recently revised by a sectional committee under the sponsorship of this society, has been officially approved as American standard by the American Engineering Standards Committee.

The code was first issued by the I.E.S. in 1915 and was revised slightly in 1918. Since June, 1920, the revision of the code has been carried out under the rules of procedure of the American Engineering Standards Committee. Pursuant to these rules, there was organized for the purpose of revising the code a sectional committee consisting of representatives of the following societies and organizations: American Gas Association, American Institute of Electrical Engineers, American Society of Mechanical Engineers, Association of Edison Illuminating Companies, Illuminating Engineering Society, International Association of Industrial Accident Boards and Commissions, National Association of Cotton Manufacturers, National Electric Light Association, National Safety Council, National Workmen's Compensation Service Bureau (now the National Bureau of Casualty and Surety Underwriters), U. S. Bureau of Standards, U. S. Department of Labor, U. S. Public Health Service.

The code is very brief, consisting of a few rules covering the minimum requirements, from the point of view of safety, for the illumination of traverse spaces during the time of use, methods for the avoidance of glare, and for exit and emergency lighting.

State lighting laws based upon the I.E.S. code have already been put into effect in Pennsylvania, New Jersey, New York, Wisconsin, Oregon, California and Ohio. The adoption of the code is now under consideration in several other states.

Copies of this code may be secured from the American Engineering Standards Committee, 29 West 39th St., New York City. Price 25 cents each.

The Slip Interference Theory of the Hardening of Metals

A General Reply to Many Questions Raised by Various Commentators—Since Martensite Is Undoubtedly Alpha Iron, the Widely Accepted Allotropic Theories Must Be Discarded—Carbon Is Held in Martensite as Dispersed Atoms

By ZAY JEFFRIES and R. S. ARCHER

SINCE the presentation of "The Slip Interference Theory of the Hardening of Metals" in the June 15, 1921, issue of this journal, several discussions have appeared.[1] It is interesting to note that the fundamental propositions of the theory were heartily indorsed by most of these scientists.

Rôle of Amorphous Metal

Heyn has received the impression that the authors attribute the hardness of cold-worked metals chiefly to amorphous metal, and dissents from such an explanation inasmuch as he does not accept the amorphous metal hypothesis. As a matter of fact, the authors attribute the hardness of cold-worked metals chiefly to the disregistry of slip planes produced by the fragmentation of the original grains. Any amorphous metal present at the slip planes and grain boundaries would of course contribute to the hardness, but is held to be at most a minor factor. Westgren also questions the importance of amorphous metal as a cause of hardness. The views of the authors on this subject have been set forth more fully in a later paper "The Amorphous Metal Hypothesis," which appeared in Chemical & Metallurgical Engineering, Oct. 12, 1921. The conclusion was there reached that the effect of amorphous metal on hardness has been greatly exaggerated by exponents of the amorphous metal hypothesis.

In the original article the authors considered that "strain" hardening is due in part to change in orientation of the crystalline fragments on deformation. At that time definite proof was lacking that change in orientation actually occurs during cold-working. This has since been supplied in an article by Bain and Jeffries (Chem. & Met. Eng., Oct. 26, 1921), in which it was shown that severe cold deformation of coarse-grained metal produces mixed orientation.

Honda thinks it improbable that a few per cent of a hard constituent in the form of highly dispersed particles can be responsible for much hardening. He compares the hardening of metal crystals by small hard particles to the hardening of gelatin by similar particles. The two cases are entirely dissimilar, as pointed out in the original paper. The case for the "critical dispersion" proposition rests largely on studies of the hardening by heat-treatment and aging of certain aluminum base alloys, as first developed by Merica, Waltenberg and Scott. Honda does not accept this explanation of the hardening of duralumin and offers an explanation of his own based on an assumed allotropy of aluminum. The experimental facts which he presents are entirely in harmony with the critical dispersion theory. We feel that the alternative hypothesis which he offers is practically untenable in view of the failure by many investigators, using all available methods of research, to find any evidence of allotropy in aluminum. It is significant that the metallurgists of the National Physical Laboratory of Teddington, England, who have been engaged for years in intensive research upon aluminum and its alloys, appear to have adopted the "dispersion" view, at least as a working hypothesis.

Hardening of Solid Solutions

The authors have attributed the hardness of solid solutions largely to increased interatomic forces, saying that in general the attraction between unlike atoms is greater than that between like atoms. Professor Sauveur has asked for evidence, or for references to evidence, that this is the case. To be more specific, the statement should be that when two elements form solid solutions or chemical compounds, the attractive forces between the unlike atoms exceed those between like atoms, since otherwise neither solution nor combination would take place. Consider a bronze containing about 7 per cent tin, for example. As cast the structure is made up of dendritic crystals rich in copper in the interior, but with the tin concentrated near the boundaries. This effect, called "coring," is found in all solid solution alloys. Now if the bronze is heated for a sufficient time at a suitable temperature, diffusion takes place and there is obtained a homogeneous solid solution of tin in copper. This shows that the attraction of copper atoms for tin atoms is greater than the attraction of copper atoms for each other, or of tin atoms for each other. If this were not the case, annealing would cause further segregation rather than an approach to homogeneity.

Constitution of Austenite

Most of the discussion relates to the authors' application of their general propositions to the specific question of the hardening of steel. Some of the points raised in this connection are vital to the explanation advanced for the hardness of martensite, while others are merely incidental.

Among the latter is the question of the condition of the carbon in the solid solution austenite. This was a subject of contention years ago, and perhaps a major-

ity of metallurgists have come to the conclusion that the carbon is dissolved "as cementite." It has been pointed out by some, however, that the evidence available was insufficient to decide one way or the other. In the light of the recent knowledge of crystal structure and of the constitution of solids, knowledge made available largely by the methods of X-ray analysis, the authors considered it probable that the carbon in austenite is present as individual atoms. The development of their conception of martensite proceeded from this view, but the essentials would not be changed if austenite were regarded as a solution of molecular iron carbide.

The view that cementite dissolves "as such" implies the presence in austenite of physical units or molecules of carbide. The X-ray work of the Braggs, Hull and others has shown that the crystals of many chemical compounds are built up of atoms arranged in definite and repeated patterns and so related that no particular combination of atoms can be picked out as constituting a physical unit or molecule. In sodium chloride, for example, each sodium atom is surrounded by six similarly related atoms of chlorine, and it cannot be said that any particular pair of atoms constitute a molecule. As a result of these studies modern chemical theory is tending to the view that in solid crystals there is in general no unit smaller than the crystal as a whole.[1] In other words, the crystal is the molecule.

There are some crystalline substances in which the unit of structure appears to be a definite group of atoms —that is, a molecule. Examples are sulphur, in which the molecule contains eight atoms, and ice, which is built up of molecules of H_2O. It is characteristic of such substances that they can be vaporized and that the molecule persists in the vapor form.

Cementite Molecule Uncertain

The structure of crystalline cementite is found by the X-ray method to be quite complex and is not yet worked out. Cementite cannot be vaporized without decomposition, and there is at present no evidence of the existence of definite molecules. In the absence of such evidence, it is most simple and logical to consider that the units in the cementite space-lattice are atoms of iron and carbon, and that there is no cementite molecule other than the crystal. The burden of proof lies with those who suppose that molecules of cementite do exist and are present in austenite.

If we assume the existence of iron carbide molecules, they must contain at least three atoms of iron and must therefore be much too large to diffuse as units through the rigid lattice of either gamma or alpha iron. Dr. Westgren contends that the diffusion of carbon in iron may take place by the progressive transfer of carbon atoms from one group of iron atoms to the next, the iron atoms remaining stationary. He considers that in each position of a carbon atom it is part of a definite group or molecule. The authors would not regard a group of iron and carbon atoms as a molecule unless the group retained its identity in such physical changes as diffusion, solution and precipitation. Their difference with Dr. Westgren is perhaps chiefly one of terminology rather than of physical fact, and does not appear to be important for practical purposes.

It may be mentioned that Dr. Irving Langmuir, who stands pre-eminent for his work on the constitution of solids, has been consulted personally by the authors and is strongly of the opinion that carbon is present in austenite as individual atoms.

Condition of Iron in Martensite

The problem of the hardening of steel is considerably simplified if we can state definitely the allotropic form of the iron in martensite. A number of reasons had long existed for supposing the iron to be of the alpha modification, and some metallurgists had formed the opinion that such was the case, but the evidence was not entirely conclusive. In their original paper on Slip Interference, the authors pointed out as a final argument the results of X-ray analysis which show without any question that *most* of the iron in martensite possesses the space-lattice characteristic of alpha iron. Professor Heyn was not convinced by the previous evidence and wrote that he awaited with interest the presentation of the X-ray work referred to. Part of this has since been described in detail in this journal, but similar results were given earlier by Dr. Arne Westgren. Dr. Westgren not only showed that gamma iron and austenite are face-centered, while alpha iron and martensite are body-centered, but he also showed that iron in the so-called beta range of temperatures has the lattice characteristic of alpha iron.

Failure to obtain the gamma iron diffraction pattern from a specimen of hardened steel does not of course show that no gamma iron is present, but merely that there is not enough gamma iron present to give a visible image on the film under the particular conditions of experiment employed. We know, as a matter of fact, that a certain hypereutectoid steel quenched drastically gave both alpha and gamma iron patterns. In this case, both austenite and martensite were visible under the microscope, and the gamma iron pattern was presumably due to the austenite. With lower carbon steels the gamma iron pattern was not found nor was austenite observed. Furthermore, the presence of a small amount of gamma iron would not complicate matters from our present viewpoint, since we cannot conceive any way in which it could act as a cause of hardness.

Grain Size of Martensite

The authors' statement that the ferrite in martensite is of submicroscopic grain size has been questioned by Professor Sauveur, who holds that insufficient evidence was given to substantiate this important point. The crystals of alpha iron, which we know constitute the bulk of martensite, form from austenite in a very short period of time during quenching. Each crystal begins as an extremely small nucleus and would have to exhibit rapid grain growth to attain any large size. When pure iron is quenched from above A_3, well-developed grains of alpha iron, easily visible under the microscope, are always obtained. These grains are formed at and just below 900 deg. C. D. J. McAdam has shown in his discussion how the velocity of grain growth in alpha iron decreases with the temperature, and how the lowering of the transformation temperature by carbon is sufficient to account for a vast decrease in grain size. He believes that any lowering below about 750 deg. C. is insignificant, because of the comparatively low velocity of grain growth in ferrite at this temperature. The authors can not quite agree to this, because the grains involved are very small, and small grains grow readily

[1] "The Constitution and Fundamental Properties of Solids and Liquids," Irving Langmuir, *J. Am. Chem. Soc.*, 1916-17.

at temperatures so low that larger grains are inert. It *is* significant, therefore, that the work of Portevin and Garvin[1] has shown that the actual temperature of formation of martensite is about 300 deg. C. This makes it still more improbable that large grains of alpha iron are formed. We may consider for comparison, although not an exact comparison, pure iron in the severely cold-worked condition. Here we know that the grain fragments are of submicroscopic size and that there are no signs of growth even after long heating at 300 deg. C.

In steel there is an additional factor not present in pure iron—namely, the obstructing effect of carbon. Whether the carbon is considered to be in the form of individual atoms, or of carbide molecules, or of minute crystals of cementite, it must have an important inhibiting effect on the growth of the grains of alpha iron.

It is thus seen that the conditions of formation of martensite favor minute grain size. Obviously there can be no visual observation of submicroscopic grains. The most direct evidence is probably to be obtained by means of the X-ray spectrometer, and in the original article the authors described how this instrument shows qualitatively that the alpha iron grains in martensite are small as compared with the parent austenite grains. The method may be capable of quantitative results, but these have not yet been obtained.

Knowing that the ferrite grains are considerably smaller than the old austenite grains, we may well ask, "By what they are represented in the structure seen under the microscope, if they are indeed large enough to be seen?" To the present writers the absence of any unit resembling "grains" is a strong indication that the grains actually are submicroscopic.[2]

Condition of Carbon in Martensite

Carbon must be present in martensite as carbon atoms, carbide molecules or crystals of cementite. Magnetic analysis of eutectoid martensite fails to show the presence of crystalline cementite. The method is capable of revealing the cementite in steel containing 0.1 per cent carbon, so we must conclude that less than this amount of carbon in eutectoid martensite is in the form of crystalline cementite. The formation of crystalline cementite is accompanied by a contraction in volume, as shown by Andrew, Rippon and Miller, and brought out in the discussion by McAdam and Styri. The tempering of martensite or the spontaneous aging of freshly hardened steel (Brush) causes a contraction in volume, indicating the formation of cementite. The tempering is known to cause the appearance of the magnetic change point of cementite at about 220 deg. C. Whether or not spontaneous aging, or long heating at 100 deg. C. would cause this has not been determined as far as we know. All lines of evidence point to the absence of crystalline cementite in the martensite of freshly hardened eutectoid or hypo-eutectoid steels, and to its formation on reheating even at temperatures so low that there is no decrease in Brinell or scleroscope hardness. What the product of this low temperature heating should be called is a matter of nomenclature. McAdam has raised a question concerning the structure produced by reheating austenitic manganese steel. The first occurrence is probably the precipitation of free cementite. At this stage the authors would say the structure consisted of austenite plus cementite. After martensitization of the austentic matrix the structure would be described as martensite plus cementite.

For those who believe austenite to contain carbide molecules, there is but one conclusion as to the condition of carbon in martensite. It must be in the form of carbide molecules which have not yet had time to associate themselves into cementite crystals. These molecules, like atoms of carbon, cannot be in equilibrium in solution in alpha iron, since the solubility of carbon in alpha iron is very low.

The authors believe that carbon is dispersed in austenite as atoms, and that the only carbide molecule is a cementite crystal. On this basis the carbon in freshly formed martensite must be largely in the form of carbon atoms, since there is no stage between the atom and the cementite crystal which we know to be absent. This view is consistent with the observation reported by Honda, that the tempering of martensite liberates an amount of heat proportioned to the carbon content of the steel and equal to about one-third of the heat given off during slow cooling at Ar_1.

It is not only possible but quite probable that some of the carbon in martensite combines with the iron to form cementite at room temperature. Brush[3] found a heat evolution at ordinary temperature in recently quenched high-carbon steel so marked that he could measure the temperature rise 35 days after quenching. The maximum temperature rise was, however, a few hours after quenching. Heyn found that the maximum rate of heat evolution in freshly quenched steel when heated occurred at about 360 deg. C. All of these results point to the substantial absence of cementite in freshly formed martensite and to a very incomplete formation in martensite aged for long periods at ordinary temperatures.

Can Internal Strain Harden?

"Internal strain" is referred to frequently as a cause of the hardness of martensite. It is seldom explained just what is meant by "internal strain," or how it could cause hardness. The term seems to mean either internal stresses or internal plastic deformation, or both, and both conditions are supposed to result from the volume change involved in hardening.

The internal stresses which we know to exist in hardening steel correspond exactly to stresses which can be set up in any pure metal or alloy by rapid temperature change. In hardened steel bursting often occurs as a result of these stresses, on account of the great brittleness of the metal, whereas a more ductile material would not show such striking signs of its stressed condition. The internal stresses can be proved to be present, however, and can be removed without changing the hardness. It has been shown without doubt that the stresses in cold-worked alpha brass can be removed without causing any appreciable change in strength or hardness. These stresses are general in character. If it is sought to attribute hardness to local stresses, it must further be remembered that the algebraic sum of all the stresses in a piece must be zero, and any effect of a local tensile stress would be exactly neutralized by a corresponding compression stress. We feel that internal stresses can be disregarded as a cause of hardness.[4]

The view that hardening is due to internal deformations analogous to cold-working is somewhat more plaus-

[1] *J. Iron and Steel Inst.*, No. 1, 1919, p. 469.

[2] A note on the grain size of martensite by Bain and Jeffries now awaits publication, and answers Prof. Sauveur, in part.—Editor.

[3] "Thermal Relations in the Treatment of Steel," by Charles F. Brush, *Trans.*, A.I.M.E., 1919.

[4] See discussion on this subject by Howe, "Metallography of Steel and Cast Iron," pp. 195-6.

ible. If we grant that the volume change is capable of producing slip on a large proportion of the possible planes, then this idea has at least this advantage: it offers as a possible mechanism for the hardening the disregistry of potential slip planes. No appreciable amorphization by such internal deformation seems likely, because if the slips are sufficiently numerous to account for the hardening, they must be very slight in extent and, as pointed out in a later paper of the authors on "The Amorphous Metal Hypothesis," such slips probably do not result in the formation of amorphous metal. Since hardness must be attributed to disregistry, or end support of slip planes, the mechanism of hardening on this basis would be very much the same as the hardening due to grain refinement.

The question is then whether the volume change which accompanies martensitization is capable of producing the necessary amount and distribution of internal slip. Although the cases are not entirely similar, we may consider in this connection the hardening effect in relation to the amount of deformation in ordinary processes of cold-working. The change in linear dimensions on hardening a 1.41 per cent carbon steel is 0.38 per cent, according to Brush. A similar change in the external dimensions of pure iron by cold-working would of course produce a practically negligible hardening effect. The exact manner in which martensitization occurs must be at present largely a matter of speculation. We may say, however, that the expansion effect begins with the formation of the less dense alpha modification. The bulk of the steel is at that time austenite, and it seems that any displacements necessary to accommodate the expansion would take place in the austenite rather than in the newly formed and fine-grained martensite. This preference should continue at least until half of the steel is transformed. The effects of any such deformation in the austenite are obliterated when that phase is transformed, except that such deformation may stimulate the formation of ferrite nuclei in the crystallographic planes of the austenite. It does not seem possible that the volume change could result in a condition in all of the newly formed constituents corresponding to extremely severe cold-working.

Fine Grain Is Principal Hardener

The authors stated that the hardness of martensite was due to two things: (1) The submicroscopic grains of ferrite and (2) the hardening effect of the carbon.

They considered that the presence of submicroscopic grains of ferrite was the major and the carbon the minor cause. According to the thesis presented pure iron by virtue of its absolute cohesion has the potentiality to produce the hardness of martensite if one could minimize the effect of planes of weakness—namely, the potential slip planes of the crystal grains. According to this view, it is possible to develop hardness either by great grain refinement or by the dispersion within larger grains of a few per cent of hard particles of critical size. Either of these conditions may be capable of developing maximum hardness. It is not contended, however, that because either condition is capable of developing maximum hardness such a state often obtains in hardened steels. Usually the critical dispersion of hard particles superimposed on a fine-grained structure will harden, and *vice versa.*

Professor Sauveur calls attention to the general similarity of the authors' conclusions concerning the hardness of martensite and certain proposals made by other investigators, particularly Le Chatelier. The authors pointed out a general similarity between their views and those of Grenet and McCance. It is not strange that these similar views should have been expressed on a subject concerning which so many speculations had been published. It is significant, however, that the opinion prevailing in spite of these theories tended almost universally toward an "allotropic" cause of hardness. Howe says in "Metallography of Steel and Cast Iron" (1916), p. 183: "What is the nature of the intermediate hardened state . . . . ? The agreement is almost universal that it is allotropic in the sense that the iron of the hardened steel is not the alpha iron familiar to us in our common annealed steel. Opinion is divided as to the nature of this allotropy."

X-Rays Have Proved That Beta Iron Does Not Exist

The information obtained by X-ray analysis now permits us to say that the iron of the hardened steel is the alpha iron familiar to us in annealed steel. With the mystic causes of hardening eliminated and with alpha iron demonstrated to be the predominant constituent of martensite, we return again to the two conditions mentioned in the original article as the logical causes of hardening. To attempt to give each of these factors its proper value quantitatively might seem to be carrying speculation too far. The authors wish to make it clear that any evaluation of these two factors would be consistent with the Slip Interference Theory of Hardening inasmuch as grain refinement and dispersion of small hard particles both harden by interfering with slip. Le Chatelier attributed most of the hardness of martensite to the carbon in solid solution. It is now known that the carbon can be present as cementite—for example, after tempering a quenched high-carbon steel at 225 deg. C.—and the steel will yet possess a hardness of the same order of magnitude as martensite. Here is a case where the great hardness cannot be attributed to carbon in solution. It is certain, however, that carbon dispersed in iron as atoms would harden the metal. That the attractive force between carbon and iron atoms is very great is proved by the hardness of cementite. These forces, *per se,* must be manifest in austenite. The extreme hardness of cementite would not be possible without great atomic attractions between iron and carbon, but it is the particular structure of crystalline cementite that makes it possible to utilize this great atomic attraction to form a hard body. Since rather large amounts of carbon in solution do not produce marked hardness in coarse-grained austenite, it seems illogical to suppose that one-third as much carbon in solution in coarse-grained ferrite would produce marked hardening.

Having reached this conclusion, it seems necessary to assume that either the fineness of ferrite grain or the association of iron and carbon atoms into small hard particles (keys) accounts for the hardness. The evidence for the existence of submicroscopic grains has been given above. There is no evidence pointing toward large grains. The evidence for assuming a substantial absence of cementite in freshly formed martensite (which is hard) has been considered. There is considerable evidence to the effect that the carbon and iron atoms in martensite associate *during tempering.* It seems logical, therefore, to attribute the major portion of the hardness of martensite to fineness of grain.

Mineral Rubber*

Results of an Investigation Designed to Bring Out the Desirable and Undesirable Properties of Mineral Rubber—Stress-Strain Data—Ultimate Elongation—Hysteresis Loss—Permanent Set—Resilience—Abrasion Loss—Elongation Under Constant Load—Rate of Plastic Flow—Recovery

By C. OLIN NORTH
The Rubber Service Laboratories Co., Akron, Ohio

MINERAL RUBBER, or MR as it is known in the trade, belongs to the great class of asphaltic products. In fact the first MR to be placed on the market in England several years ago was a variety of natural asphaltic pitch. Later it was found that the combination of this and similar substances with the harder bitumens, such as gilsonite, gave a product more in demand by the rubber industry. Shortly after the introduction of this material, the so-called asphalt and mixed-base petroleums of the mid-continent and Mexican fields began to be developed. It was found that by blowing the still residues from these oils a material similar to the natural asphalts could be obtained. This, when mixed with gilsonite, gives a satisfactory MR. In practice it is customary to mix the gilsonite and still residue previous to blowing. Recently several firms have brought out MR produced entirely from still residues.

The various grades of MR now on the market have largely been developed by the cut-and-try method. There has been practically no co-operation between MR manufacturer and consumer. In the past the manufacturer has submitted samples to the various companies with the request that they try them out. This was done and one sample was marked "the best." The same practice was continued with other consumers and when a sufficient consumption was assured, large-scale production was begun.

This is fundamentally wrong. Neither producer nor consumer obtain the maximum from the material. No one knows the effect of a slight alteration in physical properties. The purpose of this paper is to bring out the desirable and undesirable properties of MR for the benefit of others who use this material and particularly in order that those who prepare it may appreciate more fully how their product is employed and, having an appreciation of the needs of the trade, that they will endeavor to prepare a more satisfactory material, thus permitting its use in larger quantity.

Experimental Data

Materials Used

The rubber used was a carefully selected pale crêpe of excellent quality.

The MR employed was prepared from mid-continent asphalt residue and gilsonite by the usual blowing procedure. A material meeting the specifications outlined below has been in use for several years and has proved eminently satisfactory. Its aging properties are excellent and there are no difficulties met with in the factory:

Ash.....0.5 per cent
Softening point.....190 ± 10 deg. C.

Cube Method: A cube of MR is suspended on a wire in an air bath with the apex 2.5 cm. from the bottom.

Heating is at the rate of 5 deg. C. per minute. Softening point is taken as that temperature at which the MR flows down and meets the bottom.

Penetration.....70 to 90

New York Penetrometer: 150 g. weight (total weight 200 g.); time, 60 seconds; temperature, 75 deg. C. Standard New York Testing Laboratory Penetrometer Temperature maintained constant for 45 minutes previous to beginning tests.

Acetone soluble.....Maximum 55 per cent

MR crushed to 10 mesh, dissolved in 90 per cent benzene. Kahlbaum's reagent acetone or c.p. acetone redistilled over calcium chloride to which has been added two drops *N*/100 NaOH per 100 c.c. is used as a precipitant. Filter through Gooch.

It might be mentioned that this MR, in common with all other grades known to the writer, is partly converted on vulcanization to an insoluble material. Thus for the grade in question, it has been found that subsequent to vulcanization only about 45 per cent of the added MR may be removed by acetone extraction and about 10 per cent by chloroform. The color of the chloroform extract gives a distinctive test for MR, being dark and fluorescent. Approximately 45 per cent becomes insoluble.

The carbon black, zinc oxide and barytes employed were standard high quality materials.

Formulas

The stocks with but one exception consisted solely of rubber, sulphur and the material under test, and the sulphur ratio was 10 per cent on the weight of the rubber. Fillers such as MR, black, zinc oxide and barytes were added in definite volume ratios to 100 volumes of rubber.

The exception noted will be found under resilience, where for purpose of comparison a base formula of 100 pale crêpe, 5 ZnO, 6 sulphur, 3 thiocarbanilide was taken.

Milling

Batches approximated 1,000 g. in weight and were put up on a small laboratory mill. The MR was placed on the cold rolls first.

Curing

Sheets 2 mm. in thickness were vulcanized at 2½, 2¾, 3, 3¼, and 3½ hours at 141 deg. C. in a standard hydraulic press.

Methods of Conducting Tests

Complete stress-strain curves were obtained on a Scott testing machine by the two-observer method.

Stress-strain data at low elongations and hysteresis loops were obtained on a machine developed by R. D.

*Paper presented before the Division of Rubber Chemistry at the New York meeting of the American Chemical Society, Sept. 6 to 9, 1921, and published by permission of the Society.

Evans, of the Goodyear Research Laboratories. This machine consists essentially of a large balance. One arm carries a bucket into which water flows at a definite predetermined rate (2 kg. per minute).

By means of a floating siphon an outflow of 1 kg. per minute is maintained, making the rate of loading 1 kg. per minute. On the return or down curve of hysteresis loops it is only necessary to shut off the inflow of water, when the release of load is at the rate of 1 kg. per minute. The test-piece is attached to the other arm and the lower mark kept to certain point by means of a small windlass.

The method of adding load is unique. It is our belief that much of the non-agreement of usual stress-strain data is due to the fact that standard test conditions have not been maintained. In the ordinary testing machine the uniform motion of one jaw does not at all

mean that different specimens of even the same stock are tested in exactly the same manner. In the Evans machine all specimens are subjected to exactly the same rate of increase of tension per unit area of cross-section. This condition is obtained by changing the position of the bucket on the arm of the balance to correspond to the cross-section area of the test-piece. For example, with an area of 0.5 sq.cm. and a rate of 1 kg. per minute, the bucket and the test-piece being hung at 100 cm. from the knife edge, the tension is 2 kg. per sq.cm. per minute. Should the next specimen have an area of 0.49 sq.cm., the bucket is hung at 98 cm., the test-piece remaining at 100 cm. from the knife edge, and the rate of loading remains constant at 2 kg. per sq.cm. per minute. Highly gratifying results have been obtained with this machine.

Permanent set data were secured by the modified Davies-North method, which consists of three stretches to 60 per cent of the ultimate elongation, holding 3 minutes for each stretch with a 1-minute interval between; measurement 10 minutes after the third release.

Abrasion tests were made with a rough carborundum wheel 20 cm. in diameter; face 5 cm. wide; a weight of 6,800 g. placed 50 cm. from fulcrum; center of abrasion block to fulcrum, 20 cm.; abrasion block, 8.6 x 12.5 x 1.3 cm. Wheel is kept clean by a wire brush and rotates at 20 r.p.m. The volume of material removed in 200 revolutions (10 minutes) is taken as the abrasion loss.

Penetration tests were run on a simple apparatus which consists essentially of a platform mounted on a rod. The contact point is a sphere 9.5 mm. in diameter. A load of 4,500 g. is applied and the penetration of the ball into the rubber (using standard abrasion blocks) in 1 minute is read off in hundredths of a millimeter.

Elongation under constant load experiments were performed by suspending test-pieces which varied within 5 per cent in cross-section under loads of 1 and 3 kg.

The results of these experiments are given in Tables I to XII and in Figs. 1 to 12.

Discussion of Data

Stress-Strain Data

From the stress-strain data given for the 2¾-hour curve at 141 deg. C. in Tables I and IV and Fig. 1, the following observations may be made:

1. At low elongations MR is without stiffening action.

2. Up to 600 per cent elongation the individual stress-strain curves show scarcely any increase in load, but beyond this point the curves take a sharp right-angle bend. Most of the load necessary for rupture is applied in the region from 600 to 900 per cent elongation. This is characteristic of pure gum stocks. In other words, the stress-strain curves of stocks containing from 0 to 40 volumes MR per 100 volumes of rubber are quite similar.

3. Load at break (tensile strength) increases up to 7 volumes MR and then falls off slightly. The slight fall off indicates that MR is without overloading tendencies.

4. Tensile at break (corrected to area at break) accentuates the desirable properties of MR. The range of greatest efficiency is from 3 to 15 volumes and the maximum is reached at about 7 volumes MR to 100 volumes of rubber.

Volumes MR or Gas Black to 100 Volumes of Rubber

FIG. 1—STRESS-STRAIN DATA
Cure 2¾ hr. at 141 deg. C.

5. The gas black curve at 300 per cent elongation shows a straight line stiffening action very different from the 300 per cent elongation curve for MR, which is flat.

6. The gas black load at break curve is much higher than MR, but due to higher ultimate elongation (greater necking down of the MR test-pieces) the tensile at break curve for black is somewhat lower than for MR.

The conclusion from these curves is that MR in small quantities, certainly to 10 and for many purposes 15 volumes to 100 volumes of rubber, has a beneficial

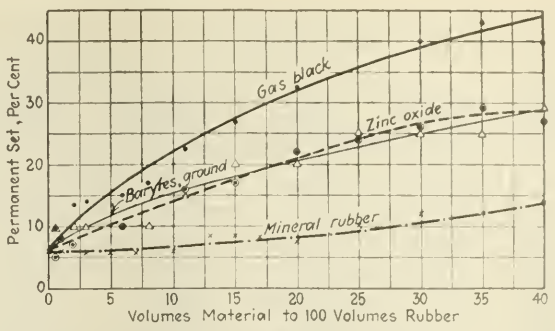

FIG. 3—PERMANENT SET

get much higher elongations—for example, in tires and tubes 100 per cent probably represents the upper limit of flexing.

The curves show the following:

(a) The variations of Scott machine readings as compared with the Evans machine show the Scott to be of little value at this elongation.

(b) First loop, Evans machine, shows a slight stiffening action not observable from Fig. 1.

(c) From a service standpoint we are not interested in the first hysteresis loop, but are greatly concerned with the behavior of our stocks after there has been sufficient flexing to bring about an equilibrium or readjustment within the stock. After five successive stretches there is little change with additional flexing.

a maximum at 7 volumes MR, beyond which there is a gradual falling off.

An interesting feature is the slight difference between the curves for the first and sixth loops. With gas black or zinc oxide the difference is quite marked. This is but another indication of the plasticity (reversible plastic flow) or MR.

Hysteresis Loss

The hysteresis loss is given in per cent based on the

Permanent Set

By permanent set is meant irreversible flow, whether it be plastic or merely due to change in position of the particles of filler. The test employed in these experiments was purposely designed to measure irreversible flow. The results are given in Table III and Fig. 3. It is well known that successive stretching, producing an internal readjustment within the test-piece, greatly increases the tensile strength and also brings out the maximum permanent set.

The stretch was placed at 60 per cent of the ultimate elongation, because it was found that most compounds could be repeatedly stretched to this elongation without having them develop flaws and fail prematurely.

As will be discussed further below, MR behaves as a supercooled liquid. Its plastic flow is reversible. Therefore this test for MR. Its curve lies considerably below those shown for black, zinc oxide and barytes.

There is a peculiar relation between permanent set and hysteresis loss as measured in this experiment. In both these tests adequate time for plastic flow is provided. The curves of hysteresis loss and permanent set are practically straight lines. The following are the slopes (tan α) taken at 25 vol. filler:

	Slope (tan α) Permanent Set	Slope (tan α) Hysteresis Loss	
MR	0.06	(6th loop)	0.06
Gas black	0.58	(3rd loop*)	0.475
Zinc oxide	0.34	(3rd loop*)	0.39

From this comparison it appears that there is more than a mere coincidence in this relationship. It is not improbable that both tests measure the same thing. It is becoming more apparent that a machine is needed which will give accurate hysteresis loops, automatically graphed within very short intervals of time. This is no more than what actually goes on in a tire on the road.

Resilience

The term resilience was first applied in rubber testing by W. B. Wiegand. It represents the energy which has been absorbed or put into the test-piece on being stretched to the point of rupture, and is determined by measuring the area between the curve and the elongation axis. For purposes of convenience this area has been converted into energy units (kg.-cm. per cu.cm.) in Table IX and Fig. 9. The MR data are taken from the curves obtained on stocks cured 2¾ hours at 141 deg. C. Gas black, though compounded in a different formula, is shown by way of comparison.

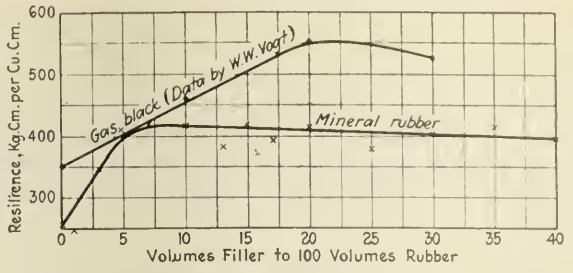

FIG. 9—RESILIENCE

The gas black curve is a straight line up to 20 volumes. The slope of this line is 0.50, which for some reason is almost the same as that of the hysteresis loss, which is 0.475.

The MR curve is somewhat different. Up to 5 volumes of MR it is a straight line (tan $\alpha = 1.5$), showing that within these limits MR does increase the energy absorption capacity of the stock. Beyond this point there is a slight falling off. However, the remainder of the curve is a straight line. This is another illustration of the peculiar inertness of MR when employed beyond the point of its maximum efficiency. As far as the writer can determine the only evidence of its presence in large quantity is in a slight raising of abrasion loss and the loginess, further discussed below.

Abrasion Loss

The effect of MR on abrasion loss has been a matter of interest for some time. The data in Table X and Fig. 10 show that with increased MR the abrasion loss increases. Penetration tests show little if any change in hardness of the stocks with increase in MR.

Elongation Under Constant Load

The old work of Schwartz (Schidrowitz, *Rubber*, p. 241) on this subject is now well known. He found that elongation under load follows the equation

$$x = a + b \ (\log \ t).$$

Where x = elongation at the end of an interval of time t.

a = elongation at the end of the first minute.

b = a constant depending on the plastic flow of the stock.

His work was checked by the writer (*Rubber Age*,

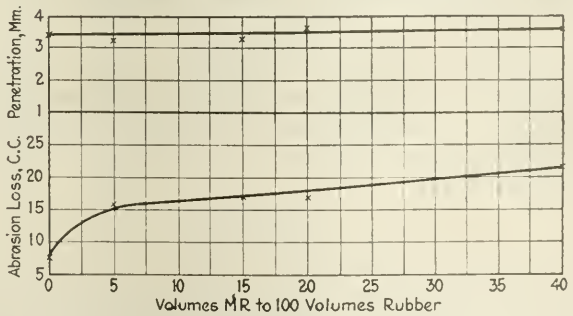

FIG. 10—PENETRATION AND ABRASION LOSS

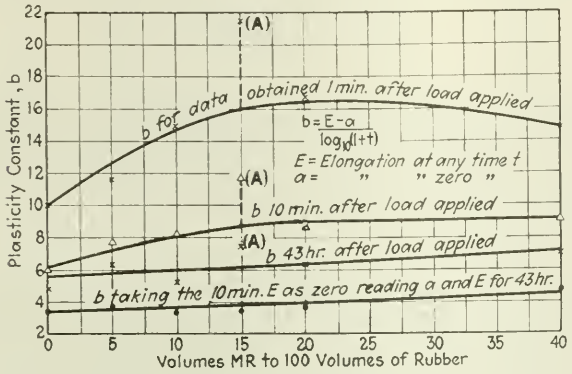
TABLE X—ABRASION LOSS

Vol. MR to 100 Vol. Rubber	Loss in Weight, G.	Sp. Gr.	Volume Abraded, c.c.	Penetration, mm.
0	7.7	0.97	7.94	3.43
5	13.3	0.98	13.6	3.38
15	16.6	0.98	17	3.43
20	16.6	0.98	17	3.52
40	21.8	1.00	21.8	3.53

Sept. 10, 1920, p. 464) who found that for heavily loaded stocks b actually was a constant and $(x - a)$ plotted against $\log_e$ time gave a straight line.

If b actually is a constant depending on the plastic flow of the stock, it would at once appear that this value determined for each stock when plotted against volumes of MR should show an increase with increased MR ratio to rubber.



Plasticity Constant, b
Volumes MR to 100 Volumes of Rubber
(A)
b for data obtained 1 min. after load applied
b = E - a / log(1+t)
E = Elongation at any time t
a = " " zero "
b 10 min. after load applied
b 43 hr. after load applied
b taking the 10 min. E as zero reading a and E for 43 hr.

FIG. 11—PLASTICITY

NOTE—The observations marked (*A*) checked in another experiment. If correct, the similarity to the jump in viscosity of olive oil-water emulsions at 80 per cent oil might be pointed out.

TABLE XI—PLASTICITY

Vol. MR to 100 Vol. Rubber	*b* Taken at 1 Min. After Load Is Applied	*b* Taken at 10 Min. After Application of Load	*b* Taken at 2,600 Min. After Application of Load	*b* Using 10 Min. Readings as Zero and 2,600 Min. (43 Hr.) After Application of Load
0	10	6	4.7	3.4
5	11.6	7.66	6.3	3.7
10	14.9	8.13	5.2	3.3
15	21.5	11.7*	7.4	3.4
20	16.5	8.6	6.24	3.7
40	14.9	9.1	7	4.66

* This value checked 10.5 on another test.

The original equation is not well written from a mathematical standpoint, since at zero time, the log of which is infinity, we have $x = a$.

If E = the elongation at any period of time t
a = elongation at zero time—i.e., when the load is just applied.
b = a constant.

$$E = a + b\ [\log_e\ (1 + t)].$$

Now in zero time the second member becomes b times zero and therefore $E = a$, which is correct.

The so-called plasticity constant then equals

$$b = \frac{E - a}{\log_e\ (1 + t)}$$

Since the question of natural or Briggs logs merely introduce a constant ratio, $\log_{10}$ may be employed. Therefore the work summarized in Table XI and Fig. 11 was done with

$$b = \frac{E - a}{\log_{10}\ (1 + t)}$$

Using this method, b values were obtained for compounds containing 0, 5, 10, 15, 20 and 40 volumes MR to 100 volumes of rubber. Values of b were calculated for readings taken 10 minutes and 2,600 minutes (143 hours) after application of load. Intermediate readings were taken, but since it was impossible to maintain temperature conditions within reasonable variation, only the four sets of values are given. It will be seen at once that the b values for 10 and 2,600 minutes are not the same. The variations range from 20 to 50 per cent. However, the readings in each group are comparable since they were made under exactly similar conditions.

Using the 10-minute values, it appears that plasticity (if b value indicates it) increases up to 15 volumes and then falls off slightly. In 2,600 minutes there can be no conclusion unless that in this time MR has reached a final position, since b values are practically constant.

In order to check this theory the readings obtained at 10 minutes were taken as zero and calculated in conjunction with those taken in 2,600 minutes. A remarkable agreement is shown. With the exception of the 40-volume compound the other constants show a variation from the mean of but 6 per cent, which points to the hypothesis that within 10 minutes the MR has become adjusted to the new conditions and therefore it is no longer a factor in b value, which now approximates that of pure gum.

If the flow of MR is really responsible for the peculiar results obtained, it would be expected that greater variation would be found shortly after load is applied. The b values calculated for readings taken 1 minute after application of load show marked variation but a progressive increase in b value up to 15 volumes of MR, after which a falling off is indicated.

Rate of Plastic Flow

In view of the fact that the b of the Schwartz equation is so obviously not a constant, it occurred to the writer that the rate of flow (millimeters extension per minute) is a much more logical method of attack.

Table XII shows the rates of extension at different times for the various MR stocks. From the data obtained when the test-pieces were suspended under a load of 1 kg., the following conclusions may be drawn:

(a) Average of all the rates determined over 43 hours show about double the pure gum velocity for all a stocks containing MR.

(b) After 43 hours suspension, flow is very small.

(c) One minute velocities show gradual increase with increase in MR up to 20 volumes, when its filling effects retards the rate.

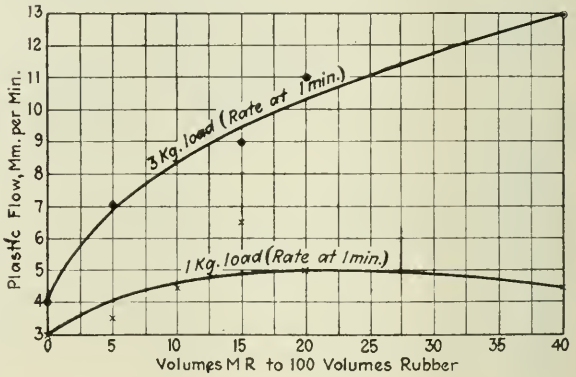


FIG. 12—RATE OF PLASTIC FLOW

The experiments with 3 kg. load were carried only to 1 hour. Due to the increased elongation the conclusions that may be drawn are somewhat different from the above. For example,

(a) The averages of all the rates determined within the hour show a gradual increase with increase in MR.

(b) A very decided increase in rate of extension with 3 kg. load in 1 minute is shown. At 40 volumes MR the pure gum velocity is more than trebled.

The rate of plastic flow appears to be quite susceptible to temperature change.

TABLE XII-A—RATE OF PLASTIC FLOW

Load 1 kg.; rate in mm. per min.

Vol. MR to 100 Vol. Rubber	Rate at 1 Min.	Rate at 10 Min.	Rate at 70 Min.	Rate at 43 Hr. (2,600 Min.)	Average Of All Rates	Average Over Entire 2,600 Min.
0	3	0.4	0.05	0.002	0.048	0.005
5	3.5	1	0.033	0.0018	0.1	0.008
10	4.5	0.6	0.033	0.0017	0.07	0.007
15	6.5	1	0.033	0.0036	0.109	0.010
20	5	0.9	0.024	0.002	0.097	0.008
40	4.5	0.85	0.01	0.004	0.094	0.009

Load 3 kg.; rate in mm. per min.

Vol. MR to 100 Vol. Rubber	Rate at 1 Min.	Rate at 11 Min.	Rate at 60 Min.	Rate Over Entire 60 Min.	Average All Rates Determined
0	4	0.5	0.03	0.217	0.74
5	7	0.5	0.054	0.334	1.31
10	Developed flaws				
15	9	0.5	0.11	0.384	1.52
20	11	0.5	0.135	0.485	1.83
40	13	0.5	0.11	0.535	2.16

From the above data it is conclusively shown that MR does increase the plastic flow of stocks containing it. The amount of this flow depends on the quantity of MR present and on the load applied.

Recovery

As mentioned above, the flow of MR is reversible. MR behaves as a true supercooled liquid. The test-pieces used in elongation under constant load experiments were measured at intervals after the recovery noted. The following conclusions are in order:

(1) Load 1 kg.; time 24 hours. (See Table XII-B.)

(a) Average rates of recovery (mm. per min.) taken from the ten readings over the 24-hour period show about the same values for pure gum and stocks containing 5 and 10 volumes MR. For 15, 20 and 40 volumes MR the rate is appreciably decreased (75 per cent of that for pure gum).

(b) Proportional recovery as shown by 1-minute readings, based on pure gum shows no change until 15 volumes MR is reached, when it drops to about 75 per cent of that shown by pure gum.

(c) Proportional recovery for the entire 24 hours shows the same recovery for MR stocks as for pure gum.

(2) Load 3 kg.; time 1 hour. (See Table XII-C.)

(a) Average of six readings during 1 hour shows about same rate of flow for pure gum and stock containing 5 volumes MR. For 15, 20 and 40 volumes the rate shows an increase with increase in MR.

(b) The proportional recovery over 1 hour is only 66 to 85 per cent of that shown by pure gum.

(c) A similar conclusion may be drawn from the 2-minute readings. The 5-volume MR and the pure gum have the same proportional recovery, but the others are considerably lower—85.5, 95 and 77.8. Had a 1-minute reading been taken, there would have been a greater contrast.

The general conclusion from these experiments is that MR does not greatly retard the ultimate recovery. However, it introduces a time factor in that the come-back within the first minute or two after release is considerably retarded when over 15 volumes of mineral rubber are introduced.

In other words, MR, being a viscous or supercooled liquid, flows with the rubber when strained and is forced back by the contraction of the rubber when released. To use a common illustration, it behaves like a door check. It not only appreciably prevents ultimate recovery but it has a decided damping effect on immediate comeback.

It is because of this property that loaded stocks containing MR are frequently logy or sluggish. In many cases this is a serious defect. For example, consider a high MR solid tire tread. In service it receives shocks of more or less magnitude all the time. If the speed is such that the tire cannot regain its original contour from blow to blow, the effect is to strain the stock in progressively increasing amounts until the elastic limit is approached and failure begins. Such a tread flattens down, cuts and gives very low life. In pneumatic tire treads, high MR produces loginess, which in turn causes tread separation and excessive wear.

This is the chief criticism of the MR of today. If it were possible to alter its physical properties so as to eliminate the tendency to produce loginess, there is little doubt that such a mineral rubber would be more extensively employed and in larger quantities.

Summary

1. MR has a beneficial effect on the physical properties of rubber when employed in proportions from 3 to 15 volumes to 100 volumes of rubber. The maximum effect is found at 7 volumes per 100 volumes of rubber. This statement is proved by experiments on tensile at break, energy input and resilience.

2. Beyond 15 volumes to 100 volumes of rubber, MR

is practically inert, as is shown by stress-strain curves, ultimate elongation, energy input and resilience.

3. MR is essentially a plastic material and while it is subject to considerable plastic flow very little of this flow is irreversible. This is demonstrated by: hysteresis loss in experiments in comparison with black and zinc oxide, permanent set experiments, elongation under constant load and recovery.

4. A remarkable agreement is shown by a comparison of the slopes of the curves for permanent set with hysteresis loss for MR, ZnO and gas black. It is recommended that a machine for automatically graphing hysteresis loops within short intervals of time be developed.

5. When present in compounds in excess of 15 volumes of MR to 100 volumes of rubber, a decided loginess is imparted. The limit at which loginess first appears is considerably dependent on the quantity of other filler present. In pure gum 15 volumes is the limit. This loginess is simply a slowing up of the recovery. MR thus acts similar to a door check, and while the eventual recovery is the same as for pure gum, this is a most serious objection to more extensive use of MR. In service complete recovery from blow to blow is prevented and the effect of successive impacts becomes more serious than if the stock had the property of rapid recovery.

6. Mineral rubber is today one of our cheapest compounding ingredients. It is hoped that the above data will prove of value to both consumer and manufacturer of MR and that the time is not far distant when an MR will be placed on the market free from any tendency to produce loginess.

Industrial Conditions in Polish Upper Silesia

A SURVEY of the industries acquired by Poland in the Upper Silesian territory by the decision of the League of Nations is given in *Commerce Reports* for Jan. 30, 1922.

The coal production for 1913 of the mines assigned to Poland was 32,829,000 tons; in 1920 these mines produced 24,637,000 tons and those in present German territory 7,114,000 tons. The net coal production of the former Polish territory (Congress Poland and Galicia) at present may be put at about 6,000,000 tons. It is estimated that, with the acquisition of the Upper Silesian territory, Poland can export about 10,000,000 tons in 1922.

Iron Ore Resources

The deposits of iron ore in Upper Silesia are nearly exhausted. However, there is every reason to believe that within the next few years the large deposits of ore in Congress Poland will be further developed and able then to furnish practically the entire ore requirements of the Upper Silesian furnaces. The present low value of German and Polish currency is an inducement to the development of these ores as against purchases from Sweden or other countries with a high rate of exchange.

Estimates of the reserves of iron ore in Congress Poland range from 300,000,000 to 600,000,000 tons. In the Radon and Kielce districts of Congress Poland there are deposits of ferromanganese ores.

In September, 1920, there were twenty-five active blast furnaces in Upper Silesia and twelve inactive. Of these, fifteen active and seven inactive furnaces are now on the Polish side. During the period April 1, 1920, to March 31, 1921, the production of pig iron was 624,000 tons, of which 407,000 tons was produced in the furnaces now located within Poland. The production of steel-converting plants for the same period was 1,147,000 tons (chiefly Martens steel), of which 838,000 tons was produced in what are now Polish plants. The production of finished steel product in the rolling mills was 793,000 tons, of which 628,000 tons was produced in present Polish property.

Zinc, Silver and Lead

Practically the entire zinc-smelting and manufacturing industry will be in Polish territory. All of the thirteen roasting plants (about 250 furnaces), the sixteen zinc smelting plants (316 furnaces) and the two lead smelters will be in Polish territory, together with five of the eight zinc-plate rolling mills. The production of raw zinc in Upper Silesia fell from 169,400 tons in 1913 to 81,400 tons in 1920. The production of lead in the two lead and silver smelting plants which are now in Poland was 41,800 tons in 1911 (the maximum year), but only 17,200 tons in 1920, while the silver production fell from 10,620 to 3,110 kilos. The total output of zinc plate in 1913 was 49,200 tons, of which the mills now allocated to Poland produced 42,500 tons. The output of all these plants in 1920 was 34,170 tons.

Other Industries

The production of sulphuric acid as a byproduct of the zinc ore roasting industry is an important acquisition for Poland. The output of sulphuric acid in 1913 was 255,600 tons (50 per cent acid), while that in 1920 was 183,300 tons. The Upper Silesian sulphuric acid will also be important for the local manufacture of superphosphates in Poland.

In connection with the acquisition of coking plants in Upper Silesia, Poland now obtains as a byproduct of that industry a large quantity of material for the manufacture of superphosphate, as well as the basis for developing a substantial chemical and dye industry. The products of dry coal distillation in Upper Silesia in 1920 included 112,413 tons of tar, 32,146 tons of ammonium sulphate and 26,153 tons of benzene. Plants producing about half of this output are now located within the boundaries of Poland. The large superphosphate plant in the Kattowitz district falls to Poland, as well as the nitrogen fertilizer factory in Chorzow. The output of materials in the Polish part of Upper Silesia is sufficient for the requirements of these plants and their finished products, together with Thomas slag from the phosphoric Polish iron ores, will go far to provide for Polish requirements of phosphatic and nitrogenous fertilizer.

Opportunities for American Export

The annexation of Silesian territory to Poland is likely to offer increased opportunities for American exports to Poland and for a change in their prevailing character. Hitherto, apart from the temporary shipments of foodstuffs to Poland, most of the American exports to that country have been raw cotton and railway equipment. The annexation of this territory will open a large field for American machinery and tools, both in Upper Silesia itself and in the industries of other parts of Poland, which will be developed as the result of the acquisition of coal and materials from that district.

Extraction of Nickel and Alumina From Cuban Iron Ores

Sulphatizing and Leaching Cuban Ore Will Extract Profitably 70 per Cent of the Nickel, 50 per Cent of the Alumina and 60 per Cent of the Manganese, Leaving a Beneficiated Iron Ore and Producing Gypsum and Iron Oxide Pigment as Byproducts

By CARLE R. HAYWARD

Associate Professor of Metallurgy, Massachusetts Institute of Technology

IRON ORE from the deposits on the north coast of Cuba contains 0.80 per cent nickel. Most of this nickel is retained in the iron during blast-furnace operations and finally reports in the steel. The nickel content of the steel made of North Coast ore is only about 1.5 per cent; whereas the nickel steels commonly used contain about 3.5 per cent. Although the presence of the small amount of nickel is claimed to be beneficial, it is not usually possible to get an additional price commensurate with the value of the nickel.

In 1914, F. A. Eustis asked the co-operation of the writer in working out a commercial process for extracting the nickel from Cuban ores. The subsequent work was conducted in the metallurgical laboratories of the Massachusetts Institute of Technology and extended over about 5 years, during which period a great mass of data was collected.

An attempt will be made in this paper to state clearly, even though briefly, all phases of a long and systematic research involving a number of novel features and resulting in several patents. Much of the work should be of general interest aside from its direct application to Cuban iron ores. During the research the writer had various assistants, to whom credit is due; H. M. Schleicher and F. O. Stillman were especially helpful. To them is due much of the success of the research. Mr. Eustis and C. M. Weld were also in close touch with the work at all times.

The Ore

The work was done on several lots of ore from the Moa Bay Iron Co., and some from Mayari deposits. Typical analyses in the natural state are as follows:

	Moa Bay	Mayari		Moa Bay	Mayari
Fe	33.25	33.30	Cr	1.17	1.26
SiO_2	2.68	4.00	Comb. H_2O	9.50	10.00
Al_2O_3	9.63	7.55	Hyg. H_2O	27.00	27.00
Ni	0.55	0.65	P, S, etc	0.73	0.50
Mn	0.48	0.50			

The ore was treated as received. There were a few hard lumps up to ½ in. in size, but the remainder was much finer. Over 80 per cent would pass a 100-mesh screen. One lot of ore which seemed most amenable to treatment was largely in the form of pellets ½ in. or less in size, formed by the balling up of fine material, but when or how this occurred is unknown.

Chloridizing Tests

The first attempt to render the nickel soluble was by subjecting the ore to a chloridizing roast in the muffle furnace shown in Fig. 1. It was mixed with salt varying from 1 to 10 per cent by weight and with pyrite varying from 0 to 10 per cent by weight. Temperatures varied from 400 to 650 deg. C., and the time of roasting varied from 2 to 6 hours. Roasted ore was leached with water and with varying strengths of HCl hot and cold. Extractions were all low (under 30 per cent) except with 10 per cent acid; in these cases an excessive amount of iron was dissolved. Chloridizing was therefore abandoned.

Leaching Tests

Numerous tests were next made with direct leaching. Leaches with ammonia gave no extraction of nickel. Hydrochloric acid was little better, as was dilute sulphuric. An extraction of 30 per cent nickel was obtained with a 10 per cent solution of sulphuric acid boiling for 5 hours, but with it came a large amount of iron. Ferric chloride and sulphate solutions were also inefficient. The results were not encouraging, so attention was turned to sulphatizing.

Sulphatizing Tests

The first tests to render the nickel soluble by sulphatizing were made by roasting the ore with pyrite. Three variables were used: temperature, time and per cent of pyrite. A series of tests between 400 and 700

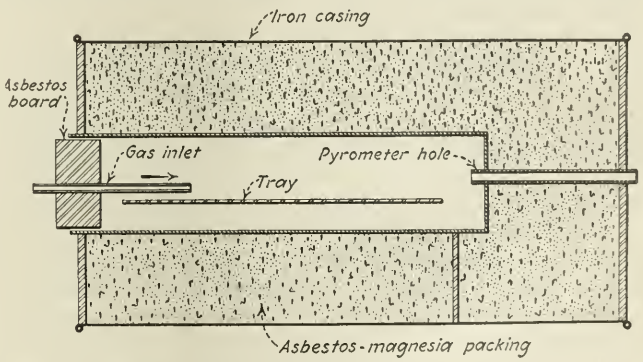

FIG. 1—4-IN. TUBE FURNACE USED FOR ROASTING EXPERIMENTS

deg. C. indicated that 475 deg. was the most suitable temperature. The nickel extractions[1] increased with time up to 4 hours, after which the extractions were practically constant. Pyrite up to 5 per cent of the weight of the ore was beneficial, but larger quantities seemed to have only slightly increased sulphatizing effect.

In most cases the extraction was between 35 and 40 per cent, 50 per cent being reached at times. Various changes were made in the procedure, such as heating slowly from a low to a high temperature and vice versa, giving the ore a preliminary oxidizing roast, giving it a preliminary reducing roast with coal, subjecting it to a preliminary heating in saturated and superheated

[1] In all the sulphatizing tests the usual method of leaching was to boil the roasted ore in a flask for about 1 hour with from three to five times its weight of water. After leaching the pulp was filtered and washed and an aliquot part of the solution taken for analysis.

steam, and so on. In some cases the extractions of nickel were distinctly lower, but in no case were they higher.

It was always possible to get better extractions by leaching with sulphuric acid solution up to 20 per cent in strength, but the amount of iron which went into solution was excessive.

After a study of the data and the methods of treatment it seemed evident that part of the nickel was in a form easily attacked by SO_2, while the remainder was more difficult to sulphatize. The pyrite was quickly exhausted and the sulphatizing power of the atmosphere in the furnace gradually lowered.

Use of Hydrofluoric Acid to Decompose Silicates

Assuming that the nickel which resisted solution was in the form of silicate (garnierite?), a series of attempts was made to decompose them. For this purpose fluorspar was mixed with the ore and the mixture roasted with pyrite. The results obtained were lower than when using pyrite alone. Addition of a small amount of steam did not improve the result; there was evidence that hydrofluoric acid was formed and attacked other minerals in preference to those of nickel.

Considerable time was spent in attempting to make garnierite soluble. Samples of that mineral were treated with hydrofluoric solutions and leached directly or after subsequent sulphatizing. In some cases sulphuric acid was used with fluorspar and the residue leached directly or sulphatized subsequently with and without steam. The highest extractions of nickel obtained were less than 40 per cent. There was evidence that the presence of hydrofluoric acid was not beneficial and in some cases was harmful.

Sulphatizing by Means of SO_2 Gas

In order to give the ore the treatment required, it seemed necessary to maintain a strong atmosphere of SO_2 throughout the period of the roast. In order to accomplish this the pyrite was put in a separate alundum boat beside the boat containing the ore and replaced by a boat of fresh pyrite every half hour. The first test showed an increase in extraction of nickel to 60 per cent. A few minor changes in manipulation and more frequent replenishing of pyrite brought the extraction up to 80 per cent. It was evident from these results that contact between ore and pyrite was not necessary and that satisfactory results could be obtained if SO_2 could be maintained in the atmosphere in the furnace.[2]

Having established the fact that contact of pyrite and ore was not necessary, it was a logical step to turn to liquid SO_2 as a constant source of gas for the experimental work. This was done with success and except where otherwise stated all subsequent work with SO_2 was carried on by introducing the gas into the furnace from a cylinder of the liquid.

In order to discover the best operating conditions a number of tests were made. First the SO_2 was used with varying amounts of air and finally with air excluded. Apparatus for accurate measurements was not available, but it was found that the highest extraction was obtained with the ratio of gas to air at about 1:4. When too much air was used the extraction of nickel dropped off; likewise with small amounts of air the extraction was very low.

Temperature in the latter tests was 475 deg. C. which had been previously established as the best temperature for sulphatizing the nickel. A series of low-temperature tests was made: It was found that passing a mixture of 3 parts air and 1 part SO_2 for 2 hours through a tube containing the ore caused the following absorption of gas:

Temp., Deg. C.	SO_2 Grams per Kg. Ore	Temp., Deg. C.	SO_2 Grams per Kg. Ore
100	19.6	200	44.5
150	27.6	350	59.0

There was a slight solubility of sulphates at 350 deg., but none at the lower temperature. This is important as indicating that if enough ore can be put in train either in the roasting furnace itself or in a preheater, very little of the SO_2 will be lost in the flue gas.

The SO_2 when mixed with illuminating gas did not render any of the nickel soluble.

Some tests were made drying the air and gas and also introducing small amounts of moisture. The best results were obtained with dry gases.

Since in practice it was probable that CO_2 would be present in the gases, some tests were made with equal amounts of air, SO_2 and CO_2. These showed no lowering of soluble nickel and there was some evidence that the CO_2 improved the extraction slightly, but this was not followed to a definite conclusion.

Use of SO_3 Gas

The solubles obtained in the experiments with SO_2 gas were all sulphates, tests for sulphites being negative. This fact made it seem advisable to try SO_3 as a sulphatizing agent.

The first tests were made by using $FeSO_4$ as a source of SO_3. Temperatures between 300 and 475 deg. C. were used with the $FeSO_4$ mixed directly with the ore or in separate boats with frequent renewal. The extractions of nickel were very low, usually not over a trace.

In order to test further the effect of SO_3, a tube of the solid anhydride was obtained and used as a source of the gas. The first test seemed encouraging when an extraction of nearly 50 per cent of the nickel was obtained at 475 deg. C. In further tests the extractions fell off to nearly zero. It is probable that in the first test some moisture was present in the cool part of the furnace so that virtually sulphuric acid was being used.

Aluminum in the Leach Liquor

Up to this time only two points had been kept in view. The main object had been to extract as much nickel as possible without rendering the residue unmarketable as an iron ore. It now seemed desirable to accept 80 per cent as the maximum Ni extraction, make a study of the composition of the leach liquor obtained, and consider methods of recovering the nickel from the solution.

Several hundred grams of ore was roasted with SO_2 gas at 475 deg. C. for 4 hours (the conditions established for maximum extraction) and leached by adding hot water and boiling 1 hour. Since the resulting solution contained only 1.5 g. nickel per liter, an attempt was made to concentrate it by evaporation, but on reducing it to about one-third its volume it became thick and of a sirupy consistency with aluminum sulphate.

It was at once evident that a high concentration of nickel could not be obtained without the removal of the aluminum. Attempts to crystallize it as an alum were

[2] This work was done in December, 1915, and January, 1916, thus antedating by about 2 years the Coolbaugh patents (U. S. Pat. 1,315,761, applied for Feb. 23, 1918) for sulphatizing the oxides produced in roasting sulphide ores with SO_2 obtained in roasting.

made, but the crystals carried nickel in prohibitive amounts. Several reagents were considered, but they did not look promising commercially; the most feasible seemed to be limestone, and numerous tests were conducted with it. It was found that simply passing the liquor over lump marble soon coated the lumps with gypsum, but by rotating the marble in a wire cylinder dipped in the liquor the aluminum could be successfully precipitated. Powdered limestone could also be used, but the lump method seemed more satisfactory. In this work it was found that the aluminum was first precipitated, followed by the iron and lastly by the nickel. One test will serve to illustrate this point.

	Solutions — Original	Solutions — After 3-hr. Contact
Fe_2O_3, grams per liter...	0.57	0.17
Al_2O_3, grams per liter...	3.21	0.02
Ni, grams per liter.....	0.30	0.31

Analysis of Air-Dried Precipitate	Per Cent
Fe_2O_3.....	2.3
Al_2O_3.....	22.1
CaO.....	19.1
SO_3.....	39.6

A few tests indicated that the aluminum could be leached from this precipitate by means of dilute H_2SO_4.

Larger Scale Roasting Work

It was thought wise that before proceeding it would be well to confirm the roasting data on a larger scale and at the same time obtain a larger quantity of leach liquor for precipitation experiments.

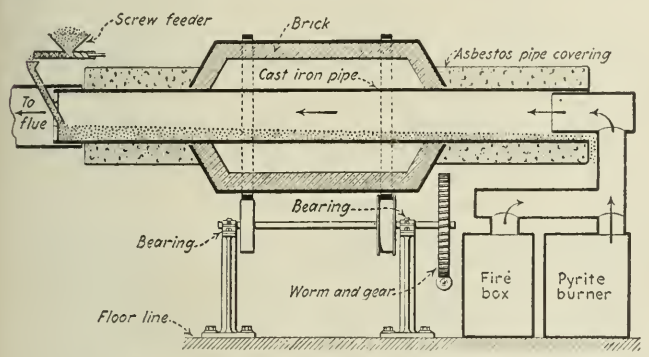

FIG. 2—MODIFIED BRUCKNER ROASTING FURNACE

The first test made was to mix a charge of 25 kg. ore with 2.5 kg. pyrite and roast it in a small brick coal-fired reverberatory furnace. It was difficult to get absolute control of the temperature, but it was kept as near as possible at 475 deg. C. for 4 hours. The results obtained from several of these tests confirmed the small-scale work that mixing the ore with pyrite would give only about 40 per cent nickel extraction.

It was therefore decided to construct a larger furnace in which SO_2 gas could be introduced. A laboratory Bruckner furnace 5 ft. long and 3 ft. in diameter was available, but since this was intermittent in operation it was used as a rotating device for a 12-in. cast-iron water pipe 12 ft. long which was inserted through the end openings as shown in Fig. 2. Firing was regulated to keep the temperature at the discharge end as near 475 deg. C. as possible; variation under regular running was ± 20 deg. C.

After numerous preliminary trials a run was made lasting 97½ hours. Ore was fed at the rate of 1.57 kg. per hour and the average extractions obtained gave Ni 53.6 per cent, Fe 2.5 per cent, Al_2O_3 51(?) per cent. It was evident that the low nickel extraction was due to the fact that the ore was subjected to the 475-deg. temperature for too short a time, since only a portion of the pulp could be maintained at this heat.

It was next decided to take the water pipe used in the previous tests, support it on suitable rollers and build a brick flue around it so it could be heated externally. This would keep the sulphatizing gases separate from the products of combustion and at the same time permit a more uniform temperature to be maintained. The feeding arrangement was kept as before, but in this case it was possible to incline the pipe slightly to facilitate the flow of ore. SO_2 was supplied from a cylinder and mixed with air. By this method nickel extractions between 70 and 80 per cent were obtained with SO_2 and air in the ratio of 1:2 by volume.

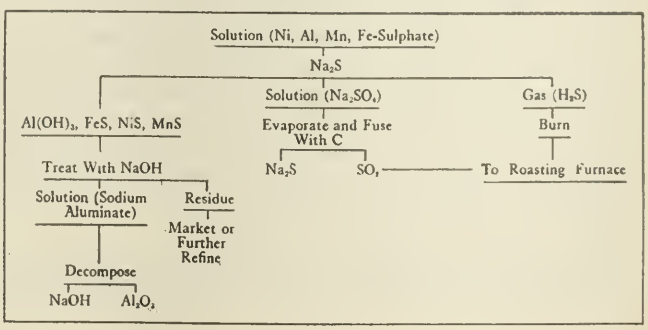
Results With Wedge Furnace

Soon after completing the experiments in the furnace just described, the Institute of Technology moved to its new site in Cambridge and a laboratory type Wedge roasting furnace was added to the metallurgical equipment. Sulphatizing tests on the Cuban iron ore were tried in this furnace with very satisfactory results. The furnace was equipped with gas burners and thermocouples on three hearths, a pipe was inserted at the lower hearth for introducing the SO_2-air mixture, and all air leaks were carefully sealed. The speed of rotation was regulated so that it took 4 hours for the ore to pass through the furnace. When the furnace was running normally, ore could be fed at the rate of 4 kg. per hour. Temperature regulation was surprisingly easy and three small gas flames kept it at the desired point. Flue gases contained only 1.5 per cent SO_2.

Numerous tests in the Wedge furnace confirmed to a surprising degree the results of the small test in the electric tube furnace. It was evident that extractions of 70 per cent nickel and 70 per cent manganese could be expected in large-scale operations. Extractions of iron could be kept as low as 10 per cent; some tests indicated 6 or 7 per cent. Aluminum extraction fluctuated between 40 and 70 per cent, depending probably on the relative amounts of clay and bauxite. Even with 10 per cent iron and only 50 per cent aluminum extracted, the iron in the residue was higher than in the original ore.

Treatment of Solutions With Na_2S

Having confirmed the small-scale roasting tests and obtained several barrels of leach liquor, experiments were next made to work out a satisfactory method for treating the solutions. A preliminary economic survey in the light of the data collected made it evident that in order to develop a commercial process it would be necessary to recover not only a fair percentage of the nickel but also the aluminum extracted from the ore and the sulphur from the roasting operation. The use of marble which has been previously discussed was therefore abandoned and some tests made with Na_2S as a precipitant. It seemed possible to work out a satisfactory process according to the following tree:



All tests indicated the entire technical feasibility of the above process. A high-grade $Al(OH)_3$ product was obtained suitable for the manufacture of metallic aluminum. The nickel-manganese-iron product was not further treated, but there seemed to be no reason why it could not be fused to a ferronickel product or otherwise treated for recovery of refined nickel. Apparently about 80 per cent of the sulphur in solution would be recovered. Unfortunately the best data obtained for the evaporation of the liquor and reduction of Na_2SO_4 to Na_2S indicated such a high cost for this step that a commercial process seemed doubtful and another method was sought.

Decomposition of Sulphates

Most metallic sulphates decompose readily when heated with carbon at red heat. It was thought that if the entire leach liquor could be evaporated to dryness and the resulting sulphates heated with carbon at a suitable temperature, the SO_2 could be recovered for direct use in the roasting furnaces and the alumina removed by leaching with caustic soda solution, from which it could be easily recovered. The residue from the caustic leach could be worked up for metallic nickel or a nickel alloy. The leach liquor used for these tests contained in grams per liter:

Al_2O_3	14.7	Cr_2O_3	1.03
NiO	1.83	Fe_2O_3	13.8
Mn	2.04	SiO_2	0.69

It is evident that the final residue would be too high in Fe_2O_3 to make a satisfactory nickel product, so some of the iron was removed by adding freshly prepared aluminum hydroxide to the liquor, which precipitated 80 per cent of the iron and all the chromium. If a stronger leach liquor is used some nickel is also precipitated by this treatment. Aluminum hydroxide remaining in the precipitate was easily removed with caustic and the residue after this treatment made a fair red pigment after proper calcining.

After the aluminum hydroxide treatment the liquor was evaporated to dryness, giving a residue of the following composition:

	Per Cent		Per Cent
Al_2O_3	16.2	Fe_2O_3	2.94
NiO	1.54	SiO_2	0.54
MnO	1.79	Hygroscopic water	3.90
Cr_2O_3	0.73	Combined water and SO_3	71.40

A series of tests was made to determine the best conditions for desulphurizing this material, and the following points were established: (1) The sulphates should first be dehydrated at approximately 400 deg. C. (2) Soft coal is the best carbonaceous material to use. About 15 per cent should be mixed with the sulphates and a blanket of coal placed on top. The latter precaution is necessary to prevent the alumina from becoming insoluble in caustic. (3) About 700 deg. C. is a satisfactory temperature, but good results were obtained between 600 and 700 deg. Roasting time is ½ hour.

It was found that the material after the above treatment still contained small quantities of sulphur, probably as basic sulphate, but this was readily removed by a dilute sulphuric acid leach. Strong caustic solution dissolves a large part of the alumina from this product, but a more complete extraction is obtained if the desulphatized material is first sintered with sodium carbonate and then treated with caustic.

Having established the feasibility of the process as far as technical considerations were concerned, the process was viewed from a commercial standpoint in the was probable after charging off the usual interest, depreciation, etc. The evaporation cost was again a very important item in the total cost and efforts were directed toward treating the leach liquor more economically.

Direct Leaching for Alumina

It has been previously noted that the presence of aluminum sulphate causes the solutions to become sirupy when concentrated and is troublesome in the recovery of the nickel. Furthermore the aluminum consumes a large part of the SO_2 used, and thus increases the expense. There are two well-known solvents for alumina —viz., caustic soda and hydrofluoric acid—and it was decided to try leaching the ore directly with these previous to sulphatizing.

A 45 per cent NaOH solution was used as in the Bayer process. On boiling the ore for 1 hour it was found possible to extract 60 per cent of the aluminum with 5 per cent of the chromium and 6 per cent of the silica. Nickel and iron were insoluble. This seemed encouraging, but considerable losses of caustic were entailed because of difficulty in washing the ore; even with large amounts of wash water much expensive caustic was lost and much evaporation would be required to concentrate the solutions. This treatment was therefore abandoned.

An attempt was made to use the Doremus hydrofluoric acid process. This process was devised for treating clay with a 15 per cent hydrofluoric acid solution. The reaction causes the temperature to rise and when it reaches a maximum the pulp is filtered. In using it on Cuban ore it was soon found that an excess of acid caused considerable solution of iron, nickel and manganese. In all tests a maximum of 50 per cent of the aluminum was rendered soluble, so tests were made using only enough hydrofluoric acid to dissolve this amount. The result was a lowered aluminum extraction. More encouraging results were obtained with a 15 per cent hydrofluoric acid solution sufficient to unite with 75 per cent of the aluminum. Under these conditions the pulp had the consistency of a thin mud. Dry ore was stirred into the solution, causing a rise in temperature of 75 deg. C. in about 2 minutes. The pulp was at once filtered, and contained at most 48 per cent of aluminum, 8.8 per cent of the iron and 10.9 per cent of the nickel and 7.8 per cent of the manganese. It was found that adding $Al(OH)_3$ to the solution after filtering would precipitate more than half of the iron, but did not affect the other constituents. Washing the ore caused much of the aluminum to hydrolyze and it was evident that great difficulty would be encountered in producing a satisfactory leach without considerable loss of acid. Sulphatizing tests on the residue were entirely satisfactory, but in view of the leaching difficulties and the contamination of the soluble by excessive solubility of iron, nickel and manganese the treatment did not look attractive.

Final Process

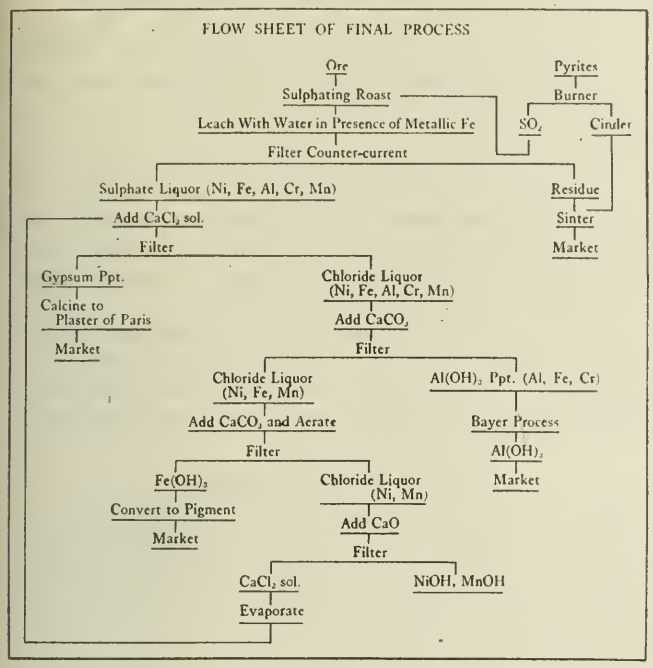
As a result of considerable further study and research a process was finally developed which was simpler than the previous treatment and so far as laboratory tests and calculations would indicate was both a technical and commercial success. It will be best understood by first presenting the flow sheet and follow it by a discussion of some of the research establishing each step.

Step 1. Tests indicated that if the ore was mined by hydraulicking, a considerable portion of the chromite in

the ore might be recovered by installing riffles in the sluiceways.

Step 2. The outstanding features of the sulphatizing roasting have already been discussed. Since the reaction is exothermic, very little heat will be required in addition to that brought in by the SO_2 gas.

Step 3. Leaching should be conducted in a suitable form of agitation tank with scrap iron present to reduce the iron in solution to the ferrous state. This makes



the solution non-corrosive and makes it possible to separate the iron and aluminum as described under step 5. After agitation the pulp goes to a filter, where after suitable washing the cake goes to a sintering machine, the product of which is sold as iron ore. If pyrite is used as a source of SO_2 the cinder is added to the ore residue for sintering.

Step 4. $CaCl_2$ solution is now added to the leach liquor. The gypsum formed accomplishes two important objects, the recovery of the sulphur in a marketable form and the elimination of a considerable portion of the water as water of crystallization, thus cutting down the amount to be evaporated. The sulphate leach liquor is also changed to chloride by this step and the separation of the constituents is facilitated.

There are several points of general interest which were brought out in studying step 4. If any of the iron in the leach liquor is in the ferric state, some of it is carried down by the gypsum and colors it brown. If the iron is all ferrous, the gypsum will be perfectly white. A long time was spent in establishing the best conditions for precipitating the gypsum, but after numerous experiments a method was finally established by which a product was obtained which would calcine properly, giving the characteristic "boil," and give a product which would set satisfactorily—in short equal to the highest grade plaster of paris.

Step 5. Several series of tests were made to study the effect of powdered marble as a precipitant. There was placed 100 c.c. of the solution in open bottles which were large enough to rotate on their sides without spilling, marble was added in varying amounts and the bottles rotated cold for 8 hours. After standing over night the tests were diluted to 250 c.c., filtered and the precipitates carefully washed. The results are given in Table I.

This table confirms what was indicated in some earlier work with lump marble—that aluminum has the greatest tendency to precipitate, with ferric iron a close second. There is much less tendency for the divalent metals to precipitate. Two courses are therefore open. Leaching the ore in the presence of scrap iron may be omitted, leaving the iron dissolved from the ore largely in the ferric condition and precipitating it with the aluminum and chromium, thus obtaining at once a separation of iron and aluminum from nickel and manganese. This has the disadvantages incident to handling highly corrosive ferric solutions and furthermore a precipitate relatively low in alumina is obtained. The other alternative is the one used in the flow sheet, where the iron is reduced to the ferrous state, the alumina precipitated relatively pure by limestone and the iron subsequently precipitated by limestone as described in the next step. The precipitation of aluminum from the reduced solution was carefully studied.

TABLE I—ANALYSIS OF FILTRATE

		Nickel		Ferrous Iron		Ferric Iron		Manganese		Alumina	
Test No.	Grams $CaCO_3$	Grams per Liter	Per Cent of Total	Grams per Liter	Per Cent of Total	Grams per Liter	Per Cent of Total	Grams per Liter	Per Cent of Total	Grams per Liter	Per Cent of Total
Original Liquor	0	1.43	100	0.75	100	6.42	100	1.30	100	?	100
1	1.0	1.42	100	0.75	100	1.28	200	1.30	100	1.17	?
2	1.5	1.42	100	0.75	100	0.26	4.0	?	?	0	0
3	2.5	1.41	99.3	0.75	100	0	0	1.30	100	0	0
4	3.0	1.40	98.6	0.75	100	0	0	1.28	100	0	0
5	3.0	1.39	97.9	0.73	97.4	0	0	1.30	100	0	0
6	4.0	1.36	95.8	0.64	85.4	0	0	1.25	96.1	0	0
7	4.5	1.30	91.6	0.42	56.0	0	0	1.09	83.9	0	0
8	5.0	1.22	85.9	0.00	0.00	0	0	?	?	0	0

It was found desirable to agitate the solution for 2 or 3 hours, otherwise the precipitate will be contaminated by basic chlorides. The precipitate obtained in this step after washing and drying is readily soluble in caustic soda solution from which pure aluminum hydroxide is precipitated by the usual methods.[3]

Best results in precipitating the aluminum with limestone were obtained by conducting the agitation in a closed pebble mill. This accomplished three principal objects: Decomposition of basic chlorides, use of less limestone, and finally exclusion of air, which last prevents oxidation and precipitation of iron. A study of the precipitation indicates that much of the aluminum is first precipitated as a basic chloride which is subsequently decomposed by the limestone. A slight excess of finely ground limestone is usually desirable.

Both hot and cold precipitation were tried. At 60 deg. C. there was less trouble with basic chlorides, but there was more loss of nickel. It seems wiser, therefore, to precipitate in the cold and give sufficient time and agitation to decompose any basic chloride which forms.

Step 6. After the aluminum has been precipitated the iron may be removed by aëration at 60 deg. C. with the addition of powdered limestone. Laboratory work was

[3]It was found that the precipitate from the leach liquor usually contained a small amount of nickel. This was unexpected and no explanation was found for it. The nickel thus precipitated is recovered by returning the residue from the caustic treatment back to the ore leaching.

carried out in a cylindrical glass cell with a canvas bottom, below which was an air chamber. The solution was kept hot by an electric coil. In a few tests no nickel was precipitated by this method, but in most cases an appreciable amount was carried down by the iron. It is probable that some condition exists where a nickel-free precipitate can be obtained, but this has not been definitely determined and at present a 15 per cent loss is assumed. The best results were obtained by adding the limestone finely pulverized and mixed with water to a thin paste. It should be added slowly. The precipitate obtained in this manner was granular and filtered very readily; after drying it was brown in color and bulky for its weight (19 lb. per cu.ft.). Analysis showed it to be practically an artificial limonite. Where a finely divided ferric oxide is desired this product should prove useful in its original state or it can be easily calcined to form a pigment.

Step 7. There now remains a $CaCl_2$ solution containtaining nickel and manganese. These are readily precipitated by burnt lime, leaving the solution to be concentrated by evaporation and returned to the gypsum precipitation.

Step 8. The nickel-manganese product may be fused to produce pig nickel or dissolved in sulphuric acid and electrolyzed, giving pure nickel cathodes and manganese dioxide at the anodes. The electrolyte is kept neutral by circulating it over fresh precipitate.[1]

The anode deposit of manganese dioxide was of sufficient purity to be used in dry cells.

Conclusions

All the foregoing results are in the nature of a summary of prolonged and systematic research. Much of the work did not lead to the desired end, but the facts brought out have metallurgical importance aside from their relation to the treatment of Cuban iron ores.

In the end a process was developed which, starting with ore from the north coast of Cuba and using as reagents pyrite (or SO_2 gas) and limestone, ends with:

1. A beneficiated iron ore.
2. Gypsum (or plaster of paris).
3. Alumina (or metallic aluminum).
4. Electrolytic nickel.
5. Manganese dioxide.
6. A pure finely divided, hydrated oxide of iron (or pigment).

An economic discussion is not within the province of this paper, but this side of the problem has been carefully considered and the results are favorable to the process.

One fact has not been mentioned in the paper which has impressed itself on all who have worked on this problem and may occur to one reading the preceding pages. This is the long, devious and rough road the research worker must often travel to reach a desired goal. In commercial research the failure of promising leads often brings the decision to give up the work. This is especially true where the men who appropriate the money are unfamiliar with the technical aspects of the problem. Again and again in the work described above there was every reason to lose hope and stop. The final success was due as much to the men who financed the operations as to those who worked in the laboratory.

[1] It was only when some of the electrolytic experiments were made that the presence of cobalt was discovered. The ore used contained a very small amount which escaped detection in the analysis. The electrolytic nickel produced contained 10 per cent cobalt and it would be necessary to make a separation if pure nickel is desired.

Reducing Eye Hazards in Industry

Definite steps to remove the eye hazard, which is increasing at an alarming rate in industry, will be taken during the coming year by the Department of Labor and Industry of Pennsylvania.

After more than 2 years' study of conditions causing eye losses, the Industrial Board has completed revision of safety standards governing head and eye protection. The head and eye code was completed and adopted by the board last July after a year of public hearings and revision and is now printed for distribution. The Division of Hygiene and Engineering performed an exhaustive investigation and prepared recommendations which it submitted to the board in July, 1920, on the eye hazard.

Seven separate occupations are enumerated in the new code where protectors are required, as follows: Oxy-acetylene and other compressed gas welding and burning, chipping, electric arc welding, grinding-wheel dressing and rough emery, iron tapping at cupola, sand and shot blasting and thermit welding.

Goggles, masks, helmets, hoods and shields are recommended as protectors for certain lines of work. In every one of the mandatory occupations goggles are required with the exception of sand and shot blasting, in which case a hood is required.

Extent of Eye Injuries

Recognition of the element of negligence in the enforcement of this code has resulted in the injection of strong arguments for the purpose of bringing home to workers and employers the danger in eye accidents. The fact that eye cases number more than all other permanent injuries put together for which compensation is paid brings home a lesson to the responsible parties. Another lesson, which confronts the workers particularly, is found in the fact that eye losses are permanent in the sense that such cases almost preclude rehabilitation in any form. A worker who loses a hand or a foot may be trained in some gainful occupation where his loss is not substantially felt, but a man who loses one or both eyes stands less chance of getting back as a producer. The employer will realize what it means when one of his employees loses an eye through having failed to take the necessary precautions when he knows that $1,005,414 was awarded last year for 677 eye losses, while $1,275,487 in compensation was awarded for 648 leg, arm, hand and foot losses combined.

Compensation is also required now under an act passed at the last session of the Pennsylvania Legislature for facial disfigurement. This hazard would be minimized by compliance with the new head and eye protection code. The first case coming under this provision of the compensation law was disposed of in an award of $600 for the loss of an ear.
